The `\ShowHook` command gives you an overview about the code chunks that have been added to a particular *hook* including information about the order they are executed. If used in interactive mode, the command stops with the usual T_EX error prompt to allow you to interface with the program. The command `\LogHook` produces the same information but simply writes it into the transcript file so that you can look at it afterwards.

Assume we have added the following three lines to the end of the preamble of Example A-4-1 on page 672:

```
\AddToHook{cmd/quote/after}[family]{\sffamily}
\AddToHookNext{cmd/quote/after}{\itshape}
\ShowHook{cmd/quote/after}
```

then this gives us the following output:

```
-> The hook 'cmd/quote/after':
> Code chunks:
>    quotesize -> \footnotesize
```

```

> family -> \sffamily
> Document-level (top-level) code (executed first):
>   -> \color {blue}
> Extra code for next invocation:
>   -> \itshape
> Rules:
>   ---
> Execution order (after reversal):
>   family, quotesize.

```

You can see that the hook now contains two named code chunks with the labels `quotesize` and `family`, and it also shows the code associated with them. The top-level code is `\color{blue}` and it is executed first, and there is `\itshape` as extra code for the next invocation. There are no special rules (for code chunk ordering — discussed below). At the end, the execution order of the chunks is given, in this case `family` followed by `quotesize`, i.e., in reverse of the declaration order. The reason for this is that `cmd/quote/after` is implemented as a reversed hook.

Important generic hooks are available out of the box

In this section we briefly discuss a number of important hooks made available by L^AT_EX. This is not an exhaustive list, but one that is intended as an overview about those hooks that you are more likely to need occasionally. There are many more, and over time L^AT_EX will get additional ones for special use cases.

Every environment offers a set of four generic hooks. There is the pair of hooks that are executed before and after the environment and that are therefore not restricted by the environment scope. These “outer” hooks are called `env/<env>/before` and `env/<env>/after`. You can think of them as being equivalent to placing your code before `\begin{env}` and after `\end{env}` on each occasion the environment is used. In addition, we have `env/<env>/begin` and `env/<env>/end`. They are both executed just in front of the code for the environment beginning and the code for its end; i.e., you can think of them as being the first code in the code arguments of `\newenvironment` or `\NewDocumentEnvironment`. Only the `/after` hook is implemented as a reversed hook; all others are normal hooks. Individual environments may offer additional hooks (e.g., the `begindocument` hooks discussed below), but these four are available with every environment.

*Generic
environment hooks:*
`env/<env>/before`
`env/<env>/after`
`env/<env>/begin`
`env/<env>/end`

All tabulars are automatically centered and typeset in Sans Serif

```

a b
c d

```

without explicitly adding center environments or `\sffamily`.

```

\AddToHook{env/tabular/before}{\begin{center}}
\AddToHook{env/tabular/after}{\end{center}}
\AddToHook{env/tabular/begin}{\sffamily}

```

All tabulars are automatically centered and typeset in Sans Serif `\begin{tabular}{ll} a & b \\ c & d \end{tabular}` without explicitly adding `\texttt{center}` environments or `\verb=\sffamily=`.

A-4-2

Generic environment hooks are never one-time hooks even with environments that are supposed to appear only once in a document. Thus, if one adds code to

such hooks after the environment has been processed, it is executed only if the environment appears again, and if that does not happen, the code is never executed.

The hooks are executed only if `\begin{env}` and `\end{env}` are used. If the environment code is executed via low-level calls to `\langle env \rangle` and `\end⟨env⟩` (e.g., to avoid the environment grouping), they are not available. If you want them available in code using this method, you would need to add them yourself, i.e., write something like

```
\UseHook{env/quote/before}\quote
...
\endquote\UseHook{env/quote/after}
```

to add the outer hooks, etc.

Generic command
hooks:
`cmd/⟨cmd⟩/before`
`cmd/⟨cmd⟩/after`

Similar to environments there are two generic hooks available for any L^AT_EX (document-level) command — in theory at least. These are `cmd/⟨cmd⟩/before` and `cmd/⟨cmd⟩/after` (the latter implemented as a reversed hook). In practice there are restrictions, and especially the `/after` hooks work only with a subset of commands. Details about these restrictions are documented in [139]. Over time more and more of them will be removed, or at least you get a suitable warning, but for now you may have to try to see if the generic hooks work for a specific command.

We give two examples. If you want all `\section` commands in your document to start a new page, then, instead of redefining this command, you could simply issue a `\newpage` in front of each, or, using the hook mechanism, specify

```
\AddToHook{cmd/section/before}{\newpage}
```

Our second example is using a `cmd/⟨cmd⟩/after` hook: remember that `\colon` in the `amsmath` package uses noticeably wider spacing compared to the usage in standard L^AT_EX. If you prefer less space there, you could always follow the command with `\!` (a negative thin space), or you could use a hook to insert it for you. In the example we use `\AddToHook` in the middle of the document to be able to show the difference. However, in a real document you should instead apply it in the preamble.

		<code>\NewCommandCopy\ltxcolon\colon % save LaTeX's definition</code>
		<code>\usepackage{amsmath}</code>
$f: A \rightarrow B$	in standard L ^A T _E X	<code>\$ f \ltxcolon A\to B \$ \hfill in standard \LaTeX \par</code>
$f: A \rightarrow B$	in amsmath	<code>\$ f \colon A\to B \$ \hfill in \texttt{amsmath} \par</code>
		<code>\AddToHook{cmd/colon/after}{\!}</code>
$f: A \rightarrow B$	in our version	<code>\$ f \colon A\to B \$ \hfill in our version</code>

A-4-3

But even that could be improved upon — after all, our change should be applied only if the `amsmath` package was loaded or will be loaded later in the preamble of the document, but not when `\colon` retains its standard L^AT_EX meaning. To achieve this with ease you need to use two (nested) generic hooks as follows:

[Ulrike]:
Hooks are fun! 

```
\AddToHook{package/amsmath/after}{\AddToHook{cmd/colon/after}{\!}}
```

Here we use a generic `package/⟨name⟩/after` hook to ensure that our `cmd` hook is

applied only after the package was loaded, if it is loaded at all. This hook is one of a dozen hooks related to file loading that can often be useful.

For each file that is loaded by L^AT_EX, regardless¹ of how this is done, e.g., with `\input`, `\include`, `\usepackage`, etc., then the following four hooks are executed. Before the file we process the general `file/before` hook followed by the more specific `file/<file>/before` hook (which is activated only if the current file to load has the name `<file>`), and after the file has been read, L^AT_EX executes the hook `file/<file>/after` and finally `file/after`. As you may have guessed, the last two are reversed hooks. The `<file>` name has to be given with its extension to be recognized, even if it is `.tex`, so this is different from the behavior of the `\input` command.

With the above four generic hooks you are already able to specify actions to be taken before or after any package or class, e.g., by using `file/array.sty/after`. However, packages and classes are a special group of files (which can be loaded only once), and for that reason they have their own set of hooks. The naming scheme is the same: `package/before`, `package/<name>/before`, `package/<name>/after`, and `package/after`, but there are two important differences to the file hooks: the specific hooks that include the package name expect the `<name>` without any extension, and, more importantly, they are implemented as one-time hooks. This is essential to make our earlier example involving `package/amsmath/after` work: if the package was already loaded, then the code in `\AddToHook` is immediately applied. If we had used a file hook instead (which is a normal hook), the code would have been stored away, waiting forever for a second invocation that would never happen. A similar set of hooks exist for class files; just replace `package/` by `class/`. You are less likely to need them, but there are a number of use cases where they can be helpful.

The final group of file-related hooks are those specific to files loaded with an `\include` command. In this case we have eight instead of the usual four hooks, due to the way this command operates. As before, there is `include/before` and `include/<name>/before`, which are executed at the beginning, but only after the `\include` command has issued a `\clearpage` to start a new page and after it has changed the `.aux` file to use the one for the include file.² When `\include` has finished reading the include file, but *before* it issues another `\clearpage` to output any deferred floats, L^AT_EX executes two extra hooks, `include/<name>/end` and `include/end`, in that order. Then comes the `\clearpage` followed by the now familiar hooks: `include/<name>/after` and `include/after`. Technically we are still in include modus; i.e., the `.aux` has not yet switched back to the one of the main document. This means any material that is typeset by any of the hooks is excluded when the file is bypassed because of an `\includeonly` statement.

All four `end` and `after` hooks are reversed hooks, and the `<name>` in the hooks has to be specified without extension. Furthermore, the specific hooks involving a `<name>` are all one-time hooks, the others normal hooks.

Generic file hooks:

```
file/before
file/<file>/before
file/<file>/after
file/after
```

Generic package hooks:

```
package/before
.../<name>/before
.../<name>/after
.../after
```

Generic class hooks:

```
class/before
.../<name>/before
.../<name>/after
.../after
```

Generic include hooks:

```
include/before
.../<name>/before
.../<name>/end
.../end
.../<name>/after
.../after
.../excluded
.../<name>/excluded
```

¹This is a bit of a white lie: if a file is read using internal low-level methods, such as `\@input` or `\openin`, no hooks are executed. But these are not operations available on the document level.

²If you really need to place code before that, you can use the hook `cmd/include/before`, i.e., the generic command hook for `\include`.

The six hooks for `\include` we have discussed so far are executed only if the file is included (or at least an attempt is made to include it). They are bypassed if the file is explicitly excluded, i.e., if an `\includeonly` statement is given that does not contain the file `<name>`. In that case the hooks `include/excluded` and `include/<name>/excluded` are executed instead in that order.

Special hooks available in the document environment

Until 2020 L^AT_EX offered exactly two hooks in the document environment that one could use to add code to: `\AtBeginDocument` and `\AtEndDocument`.

Experiences over the years have shown that these two hooks and the place where they are executed were not enough, and as part of adding the general hook management system a number of additional hooks have been added. The places for these hooks have been chosen to provide the same support as previously offered by external packages, such as `etoolbox` and others that augmented document to gain better control.

Hooks inside
`\begin{document}:`
`.../before`
`begindocument`
`.../end`

Inside `\begin{document}` there are now three hooks available to the programmer: `begindocument/before` is executed at the very start of the environment and could be thought of as ending the preamble. The `begindocument` hook is executed next, after the `.aux` file has been read in and most initializations are done. They can therefore be inspected and altered by the hook code. This is the place to which `\AtBeginDocument` writes, which these days is implemented by adding to this hook. After this there are a small number of further initializations that should not be altered and are therefore coming later. Neither hook should add material for typesetting because we are still in L^AT_EX's initialization phase and not in the document body. If such material needs to be added to the document body, use the next hook instead.

The final hook is `begindocument/end`, which is executed at the end, in other words, at the beginning of the document body. The only command that follows it is `\ignorespaces`. It can therefore be used (for example by a document class) to add typesetting material at the start of the document by placing it into this hook.

Draft material

As any dedicated reader can clearly see, the Ideal of practical reason is a representation of, as far as I know, the things in themselves; as I have shown elsewhere, the phenomena should only be used as a canon for our understanding.

```
% Assume this to be inside the document
% class, for example, as part of a ‘‘draft’’
% option declaration:
\AddToHook{begindocument/end}
    {\begin{center}%
     \fbox{Draft material}%
    \end{center}}
```

```
\usepackage{kantlipsum}
```

```
\kant[1][1] % the text by the author ...
```

A-4-4

All three hooks are implemented as one-time hooks. The generic hooks executed by `\begin` also exist, i.e., `env/document/before` and `env/document/begin`, but with this special environment it is better use the dedicated one-time hooks above.

L^AT_EX_{2 ϵ} always provided the command `\AtEndDocument` to add code to the execution of `\end{document}` just in front of the code that is normally executed there. While this was a big improvement over the situation in L^AT_EX_{2.09}, it was not flexible enough for a number of use cases, and so packages such as `etoolbox`, `atveryend`, and others patched the kernel code to add additional points where code could be hooked into. Patching kernel code in packages is always problematical because it leads to conflicts (code availability, ordering of patches, incompatible patches, etc.). For this reason these patches have been backported to the L^AT_EX kernel, and a number of additional hooks have been added to allow packages to add code in various places in a controlled way without the need for overwriting or patching the core code.

*Hooks inside
`\end{document}`:*
`enddocument`
`.../afterlastpage`
`.../afteraux`
`.../info`
`.../end`

The code starts as before by adding a `\par` and then executing the `enddocument` hook (which is the hook `\AtEndDocument` writes to). At this point there may be still unprocessed material (e.g., floats on the deferlist or text material in the galley), and the hook may add further material to be typeset. This first hook is the only one that is allowed to add material to be typeset; all later ones are supposed to only contain code that executes certain housekeeping actions. After it, `\clearpage` is called to ensure that all such material gets typeset. If there is nothing waiting, this `\clearpage` has no effect.

The next hook is `enddocument/afterlastpage`. As the name indicates, this hook should not receive code that generates material for further pages. It is the right place to do some final housekeeping and possibly write out some information to the `.aux` file (which is still open at this point to receive data, but because there are no further pages, you need to write to it using `\immediate\write`). It is also the correct place to set up any testing code to be run when the `.aux` file is re-read next. Once this hook has been executed, the `.aux` file is closed for writing and then read back in to do some tests (e.g., looking for missing references or duplicated labels, etc.).

After the `.aux` file reprocessing has finished, the hook `enddocument/afteraux` is executed. It is therefore a possible place for doing final checks and displaying information to the user. However, for the latter you might prefer one of the next hooks so that your information is shown after the (possibly longish) list of files if that got requested via `\listfiles`.

Directly following the previous hook, the hook `enddocument/info` is executed. It is meant to receive code that writes final information messages to the terminal. This hook already contains some code added by the kernel (under the labels `kernel/filelist` and `kernel/warnings`), namely, the list of files when `\listfiles` has been used and the warnings for duplicate labels, missing references, font substitutions, etc. Instead of the two hooks in succession, there could have been just a single hook, but then going before or after the kernel material would require setting up dedicated hook rules, while with two hooks you can simply select the appropriate hook.

Near the end, just before L^AT_EX invokes T_EX's endgame processing, there is yet another hook named `enddocument/end`. Whether or not this will ever be needed remains to be seen, it was mainly provided because it was already part of one of the packages that was replaced by adding the hook management to L^AT_EX.

Hooks provided for `\shipout` operations

Hooks inside
`\shipout`:
`shipout/before`
`.../background`
`.../foreground`
`shipout`
`.../firstpage`
`.../lastpage`
`.../after`

The process that ships out the final pages also offers a number of hooks. Two are of possible interest for authors; the others are most likely needed only in packages that alter the behavior of L^AT_EX's output routine. The hooks that are generally useful are `shipout/background` and `shipout/foreground`. Both allow you to place some material onto each page, either in the background, i.e., behind the normal page material, or in the foreground, i.e., on top of it and thus partially hiding the text.

Both hooks add a picture environment with the (0,0) coordinate in the top-left corner of the page and locally set a `\unitlength` of 1pt. The hooks should therefore contain only `\put` commands or other commands suitable within a picture environment; see Section 8.3 on page 1602 for possibilities.

With the starting point being the top-left corner of the page, your vertical coordinate values should be negative, which needs getting used to — if your material does not show up, it is rather too likely that you placed it outside the page by using a positive value. During the `shipout` the background picture is printed first, then the content of the page, and finally the foreground picture, each overwriting the other.

In the next example we use the `shipout/background` hook to add a logo into the background of every page. Note the absolute coordinates `.5\paperwidth` and `-.5\paperheight` to position ourselves flat in the middle of the page, and then we used a `\makebox(0,0)` construction to center the graphic around that point. To also exhibit the `shipout/foreground` hook we place a colored box at the bottom left, however, this time only on the second page by using `\AddToHookNext` instead of `\AddToHook`. Of course, you cannot seriously censor material this way. First of all the page pictures are static and the text is dynamic, but more importantly the text is still inside the PDF and only hidden through overprinting.

As any dedicated reader can clearly see, the Ideal of practical reason is a representation of, as far as I know, the things in themselves; as I have shown elsewhere, the phenomena should only be used as a canon for our understanding. The par-

alogisms of practical reason are what first give rise to the architectonic of practical reason.

As will easily be shown in the next section, reason would thereby be made to contradict, in view of these

Censor this! s, the Ideal of

```
\usepackage{kantlipsum,graphicx,color}
\AddToHook{shipout/background}
{\put(.5\paperwidth,-.5\paperheight)
 {\makebox(0,0){\includegraphics
 [scale=.7]{latex-logo}}}}
\kant[1][1-2] % text by the author ...
\AddToHookNext{shipout/foreground}
{\put(0,-\paperheight)
 {\colorbox{red}{Censor this!}}}
\kant[1][3] % ... more text ...
```

A-4-5

The remaining five hooks are intended for rather specialized actions. The hook `shipout/firstpage` places material at the very beginning of the output file and the hook `shipout/lastpage` at the very end — both should contain only `\special` or similar commands needed for post processors handling the `.dvi` or `.pdf` output.¹

The hook `shipout/before` can be used to manipulate the collected page box before it is being shipped out (or even discard it); for details, see [139]. It can also be used by packages to undo their modifications if they should not be active when

¹The `shipout/firstpage` hook can also be set using the command `\AtBeginDvi`.

the page is processing during shipout. For example, some packages, noticeably those that produce verbatim text, alter the definition of active characters, and these settings should not be used while a page is built just because L^AT_EX decided to end the page in the middle of such an environment. If such settings remain active, this can lead to very strange errors, because during the shipout `\write` statements may be executed, and they would find themselves suddenly in a “verbatim” context.

The hook `shipout` has a similar purpose but is executed right in front of the page being shipped out, i.e., after any foreground or background material has been added. Finally, `shipout/after` is called after the current page has been shipped out.

Note that it is not possible (or advisable) to try to use these hooks to typeset material with the intention of returning it to the main vertical list. It will go wrong and give unexpected results in many cases — for starters it will appear after the current page, not before, and with a high likelihood the vertical spacing will be wrong!

 *None of these hooks should be used for typesetting*

Other hooks

L^AT_EX also offers other hooks, e.g., for paragraph processing¹ or font selection, but most of them are for special use cases and are of little interest to most users or even package developers. Further areas are expected to get hooks added over time. This “hookification” is under active development, and the current state and pointers to the documentation are given in [139].

A.4.2 Declaring hooks and using them in code

Up to this point we have looked at how to use existing hooks that are provided by packages or the L^AT_EX kernel. We now look briefly at what is necessary to define new hooks and use them in your own package code. There is more to it than we can cover here — if in doubt, refer to [139] for additional details.

Hooks have global data structures associated with them, and it is therefore essential that hooks used for different tasks are distinct, i.e., have unique names. This is why they need to be declared beforehand. If two packages declare the same name as a hook, then they cannot be used together in the same document. It is therefore important to choose a good name, preferably one that is directly related to the command or environment in which the hook is used to avoid making packages unnecessarily incompatible with each other.

```
\NewHook{hook}      \NewReversedHook{hook}
\NewMirroredHookPair{hook1}{hook2}
```

A new hook has to be declared with `\NewHook`, or, if we want to declare it as a reversed hook, then with `\NewReversedHook`. Given that reversed hooks are usually (but not always) paired with a normal hook, there is also `\NewMirroredHookPair`, which is just a shorthand for calling the other two declarations in succession.

¹ An example for the `para/before` hook is shown on page –I 429.

This covers normal and reversed hooks, but as mentioned earlier, there are also generic hooks. These are not declared beforehand because “generic” means they exist with a wide variety of names, and that makes it difficult to predeclare them. They rely on the fact that their names are structured and are therefore likely to be unique. How to provide new generic hooks is discussed later.

`\UseHook{hook}` `\UseOneTimeHook{hook}`

In your package you execute a normal *hook* code by calling `\UseHook`. This executes all code chunks defined for the hook in a predefined order (in most cases in the order the chunks got declared), followed by the code declared with `\AddToHookNext`, if any. The latter is then automatically removed after usage.

If the hook is intended to be a one-time hook, you call it with `\UseOneTimeHook` instead. In this case the hook chunks are executed as described above, but additionally L^AT_EX records that the hook has been executed. This has the effect that any further calls to `\UseOneTimeHook` or `\UseHook` with that *hook* name as the argument do nothing. Additionally, any future `\AddToHook` declaration for that name executes immediately instead of being stored away.¹

If you use `\UseHook` or `\UseOneTimeHook` without declaring the hook, then the call is simply ignored — see below for when this makes sense.

Setting up additional generic hooks

The generic hooks provided by L^AT_EX, i.e., for `cmd`, `env`, `file`, `package`, `class`, and `include`, are available out of the box. You only have to use `\AddToHook` to add code to them, but you do not have to add `\UseHook` or `\UseOneTimeHook` to your code, because this is already done for you (or, in the case of `cmd` hooks, the command is patched at `\begin{document}`), if necessary).

However, if you want to offer your own generic hooks in your code, the situation is slightly different. You provide for such a generic hook by using `\UseHook` or `\UseOneTimeHook`, but *without declaring the hook* with `\NewHook`. As mentioned earlier, a call to `\UseHook` with an undeclared hook name does nothing. So as an additional setup step, you need to explicitly activate the generic hook. Note that a generic hook produced in this way is always a normal hook.

For a truly generic hook, with a variable part in the hook name, an up-front activation would be difficult or impossible, because you typically do not know what kind of variable parts may come up in real documents. For example, `babel` may want to provide hooks such as `babel/⟨language⟩/afterextras`. Language support in `babel` is often done through external language packages. Thus, doing the activation for all languages inside the core `babel` code is not a viable approach. Instead, it needs to be done by such language packages (or by the user who wants to use a particular hook).

Because the hooks are not declared with `\NewHook`, their names should be carefully chosen to ensure that they are (likely to be) unique. Best practice is to

¹ As mentioned earlier, calls to `\AddToHookNext` have a different behavior: they are simply ignored if issued too late.

include the package or command name as was done in the `babel` example.

```
\ActivateGenericHook{hook}
```

Once this declaration is given, the *hook* is activated, and its use with `\UseHook` or `\UseOneTimeHook` takes effect. In contrast to `\NewHook` (which also activates a hook), this declaration can be used multiple times.

As an example, we color German words in blue inside an English document by adding a `\color` statement to the generic hook `babel/ngerman/afterextras` and activate the hook so that it is used. Note that such declarations can happen even before `babel` is loaded; thus, a class can make adjustments for `babel` but leave it up to the user whether `babel` is loaded or not.

```
\AddToHook{babel/ngerman/afterextras}{\color{blue}}
\ActivateGenericHook{babel/ngerman/afterextras}
```

Text with **deutschen Worten** in the middle of **englischem Text**.

```
\usepackage{color} \usepackage[ngerman,english]{babel}
Text with \foreignlanguage{ngerman}{deutschen Worten} in
the middle of \foreignlanguage{ngerman}{englischem Text}.
```

A-4-6

Returning to black in the previous example worked only because the German text was always limited by the scope of the `\foreignlanguage` command. If we had used `\selectlanguage` or nested commands instead, the color change would persist, because none of the other languages undo it. Thus, to work in a more complex scenario, we need similar declarations for any other language to reset the color.

The generic command hooks `cmd/⟨cmd⟩/before` and `cmd/⟨cmd⟩/after` are automatically patched into the command `⟨cmd⟩` in case code has been added to the hook, i.e., a `\UseHook` command is added to the beginning or end of the `⟨cmd⟩` code and the hook is activated. As mentioned, for some commands such patching is not possible, and to avoid the user getting a low-level failure, L^AT_EX has the declaration `\DisableGenericHook`. It is mainly intended for command hooks that would fail, but there may be use cases where disabling other generic hooks is useful too.

 *Adjusting the use of ⟨cmd⟩ hooks*

Instead of disabling a nonfunctional command hook, a package developer may choose to explicitly add the `\UseHook` call in an appropriate place when defining the `⟨cmd⟩`. If that is done, it is important to also explicitly declare the hook with either `\NewHook` or `\NewReversedHook` to make it “nongeneric”, because that prevents L^AT_EX from later patching the `⟨cmd⟩` and incorrectly adding another `\UseHook`.

Reordering code chunks in hooks

The default assumption is that if several packages add data to the same hook, the order of the code execution is of no importance. Of course, in real life this is unfortunately often not true, which accounts for the many package loading issues people had in the past, for which you then got advice on the Internet such as “load package A after package B and load package C always last”. In many cases the underlying reason was that different `\AtBeginDocument` statements had to be executed in the right order.

With the new hook management system this can now often be resolved up front. If you know that the code added to a certain hook needs to be run before or after the code added by some other package, you can declare a rule that tells the hook management to arrange for the required order. If the other package is not loaded, the rule is simply ignored, and it also does not hurt if both packages declare such a rule (as long as the rules are not in conflict with each other).

```
\DeclareHookRule{hook}{label1}{relation}{label2}
```

With this declaration you define a relation between *label₁* and *label₂* for a given *hook*. There can be only a single relation between two labels for a given hook; i.e., a later `\DeclareHookRule` overwrites any previous declaration. The supported *relations* are the following:

before or **<** Code for *label₁* comes before code for *label₂*.

after or **>** Code for *label₁* comes after code for *label₂*.

incompatible-warning Only code for either *label₁* or *label₂* can appear for that hook (a way to say that two packages—or parts of them—are incompatible). A warning is raised if both labels appear in the same hook.

incompatible-error Like **incompatible-warning**, but instead of a warning, a L^AT_EX error is raised, and the code for both labels is dropped from that hook until the conflict is resolved.

voids Code for *label₁* overwrites code for *label₂*. More precisely, code for *label₂* is dropped for that hook. This can be used, for example, if one package is a superset in functionality of another one and therefore wants to undo code in some hook and replace it with its own version.

unrelated The order of code for *label₁* and *label₂* is irrelevant. This rule is there to undo an incorrect rule specified earlier.

As an example we find the following declaration in the `fnpct` package, which ensures that inside the hook `begindocument` the code labeled `fnpct` runs after any code labeled `hyperref` if present:

```
\DeclareHookRule{begindocument}{fnpct}{after}{hyperref}
```

Remember that the default label for code chunks is the current package or class name when `\AddToHook` is used without specifying an explicit label. Thus in most cases, code chunks are labeled with the package or class name from which they originate. Therefore, this declaration really means that inside `begindocument`, the code from the `hyperref` should run before the code from `fnpct` so that the latter can make use of it, regardless of the loading order of the two packages.

The top-level label, which by default is used to label code added in the preamble or in the document body to a hook, is special in that it is always executed *last* in a normal hook (and first in a reversed hook). It is therefore not permitted to use this label in a hook rule. The reason is that hook declarations made in such places are typically done to overwrite code by packages to the hook, and the preamble code therefore needs to come later. If that is not the right place for code to be executed, you can give it an explicit label and then add a `\DeclareHookRule` to ensure that it is executed at the right point.

 *The top-level label is special*

```
\DeclareDefaultHookRule{label1}{relation}{label2}
```

The `\DeclareHookRule` defines a relation between two labels for a single hook. However, if there are many hooks for which this relationship holds, then it is inefficient to be forced to declare them repeatedly for all hooks. To simplify the input, as well as to clarify the situation, there is `\DeclareDefaultHookRule` that defines a default relationship between *label₁* and *label₂* for all hooks in which these labels are used. This is useful for cases where one package has a specific relation to some other package; e.g., it is incompatible or always voids or needs a special ordering with *before* or *after*. If necessary, you can always overwrite that default for individual hooks by also giving a `\DeclareHookRule` for a specific hook.

A.5 Control structure extensions

This section starts with the `iftex` package that allows you to write code that varies based on the \TeX engine it gets used with. We then describe two packages that are distributed as part of the $\text{\LaTeX 2}_{\epsilon}$ core distribution since its introduction in 1994. Consequently, you find them used as part of many packages and classes.

The first, `calc`, extends \LaTeX to support infix arithmetic in many commands that expect a number or a dimension as an argument. Although there are nowadays other possibilities offered by newer \TeX engines and also by \LaTeX directly (see Section A.2.5 on page 657), this remains useful and is used in a number of examples in this book.

The second, `ifthen`, defines a number of commands for conditional processing. While this was a big step forward back then and was therefore used a lot in the past, it has a number of serious limitations and a somewhat clumsy syntax. For this reason we recommend it only for very simple tasks (if at all). A lot of its functionality can already be achieved by using the new powerful command declarations described in Section A.1.4 on page 632, and for serious coding you have a much better solution with the L3 programming layer, which offers many more sophisticated conditionals that do not exhibit the limitations of `ifthen`. We mainly kept it in the book because of its wide use in packages, so it helps to have some basic understanding of its functionality.

 *ifthen is not recommended for new package developments*

A.5.1 `iftex` — On which \TeX engine are we running on?

With different \TeX engines available — each of which offering one or the other feature not available in other engines — it is sometimes necessary to ensure that a document is processed with a certain engine or one from a group of engines, i.e., one of the

Unicode engines. L^AT_EX tries fairly hard to abstract from engine peculiarities, but even so, you may find that you want to write some commands that need different implementations for different engines.

To accomplish either task, several people have written small packages that define tests to figure out if your document is processed by a specific engine. The `iftex` package (by the L^AT_EX Project Team) is a consolidation package that provides such tests for most T_EX engines in use, so it has effectively many authors, because it combines ideas from Heiko Oberdiek (`ifluatex`, `ifvtex`, and `ifptex`), Martin Scharrer (`ifetex`), YATO Takayuki (`ifptex`), Vafa Khalighi (`iftex` version 0.2), and Will Robertson (`ifxetex`) in a single package, rendering the others (except `ifptex`, see below) essentially obsolete by providing all of their functionality.

All tests are constructed in the same manner and rely only on low-level constructs in order to function not only in L^AT_EX but in any flavor of T_EX, hence the slightly unusual syntax. Here is an example to test for pdfT_EX:

```
\ifPDFTeX
  code to execute if the engine is pdfTeX
\else
  code to execute for all other engines
\fi
```

In the *else* part you can then make further tests to distinguish between other engines as necessary. All `\if . . .` tests exist in two forms: mixed-case as above or with a name using only lowercase characters, e.g., `\ifpdfTeX`, if you prefer that. In the listing below we give only the mixed-case names because not all of them might be obvious (the lowercase ones hopefully are).

<code>\ifXeTeX</code>	<code>\ifLuaTeX</code>	<code>\ifLuaHBTeX</code>	<code>\ifTUTeX</code>
-----------------------	------------------------	--------------------------	-----------------------

These test if the Unicode engines X_YL^AT_EX or LuaT_EX are used. `\ifLuaTeX` is true regardless of any extension being activated, while `\ifLuaHBTeX` is true only if the HarfBuzz library is available in the LuaT_EX engine.

The `\ifTUTeX` test is not strictly testing for an engine variant: it will be true if the current engine supports the primitive `\Umathchardef`, which is the case for X_YL^AT_EX and LuaT_EX (and possibly other engines supporting Unicode), so you could write something like

```
\ifTUTeX
  \usepackage{fontspec,unicode-math}
  \setmainfont{TeX Gyre Termes} \setmathfont{Stix Two Math}
\else
  \usepackage{newtxtext,newtxmath}
\fi
```

to make your document work with X_YL^AT_EX, LuaT_EX, and pdfT_EX by selecting different font packages depending on the engine.

<code>\ifpTeX</code>	<code>\ifeTeX</code>	<code>\ifupTeX</code>	<code>\ifpTeXng</code>
----------------------	----------------------	-----------------------	------------------------

`\ifpTeX` is true when any of the pTeX engine variants (engines that support Japanese input encodings) are used. \LaTeX requires the availability of the eTeX extensions, which is not the case with all variants. For this one can could test with `\ifeTeX`. Similarly, `\ifupTeX` tests for any of the upTeX variants (engines that support Japanese but with Unicode input encoding) — again you may additionally want to check for the eTeX extensions. Finally, `\ifpTeXng` tests for pTeX-ng (Asiatic pTeX), `\ifVTeX` for the commercial VTeX engine, and `\ifAlephTeX` for Aleph (the successor of Omega).

Note that while the `iftex` package provides basic support for detecting Japanese TeX variants, it is not a full replacement for the `ifptex` package, which has many more detailed tests for pTeX variants and is recommended if you need granular control over the Japanese TeX system in use.

<code>\RequirePDFTeX</code>	<code>\RequireXeTeX</code>	<code>\RequireLuaTeX</code>
<code>\RequireLuaHBTeX</code>	<code>\RequireTUTeX</code>	<code>...</code>

If your document (or package) is usable only with a specific engine, then you can use one of the `\Require..` commands instead of the above tests. They test for the specific engine and stop with a suitable error message if not.

<code>\ifpdf</code>

Several engines can produce `.pdf` or `.dvi` output and make this configurable, for example, through `\pdfoutput` that can be set in the format or at the very start of the document. `\ifpdf` can be used to test if the output format is PDF.

A.5.2 calc — Arithmetic calculations

The package `calc` (by Kresten Thorup and Frank Jensen) contains a set of macros for enhanced arithmetic in \LaTeX . The usual arithmetic in TeX is done by simple low-level operations like `\advance` and `\multiply`. This package defines an infix notation arithmetic for \LaTeX . In fact, it reimplements the \LaTeX commands `\setcounter`, `\addtocounter`, `\setlength`, and `\addtolength` so that they can accept integer and length expressions rather than simple numbers and lengths.

An integer expression can contain integer numbers, TeX's integer registers, \LaTeX 's counters (e.g., `\value{ctr}`), parentheses, and binary operators (`-`, `+`, `*`, `/`). For instance, to double a counter value and additionally advance it by five:

```
\usepackage{csquotes,calc}
\newcounter{private}
\setcounter{private}{2} % initial setting for the example
The value is currently \enquote{\theprivate}.\
\setcounter{private}{\value{private}*2 + 5}
The value has now changed to \enquote{\theprivate}.
```

The value is currently “2”.

A-5-1

The value has now changed to “9”.

An example is the definition of a command to print the time (note that the T_EX register `\time` contains the number of minutes since midnight):

```
\usepackage{calc}
\newcounter{hours}\newcounter{minutes}
\newcommand\printtime{\setcounter{hours}{\time/60}%
\setcounter{minutes}{\time-\value{hours}*60}%
\thehours h \theminutes min}
```

The time is 14h 16min.

The time is `\printtime`.

A-5-2

When dealing with lengths, the subexpressions that are added or subtracted must be of the same type. That is, you cannot have “2cm+4”, but an expression like “2cm+4pt” is legal because both subexpressions have dimensions. You can only divide or multiply by integers, so “2cm*4” is a legal subexpression, but “2cm*4pt” is forbidden. Also, the length part must come first in an expression; thus, “4*2cm” is not allowed.

The commands described above allow you to calculate the width of one column in an n -column layout using the following single command (supposing that the variable n is stored as the first argument of a L^AT_EX macro):

```
\setlength\linewidth{(\textwidth-\columnsep*(#1-1))/#1}
```

The restriction that you can only multiply and divide by integers has been relaxed for calculations on lengths (dimensions). Those operations are allowed with real numbers.

```
\real{decimal constant} \ratio{length expression}{length expression}
```

A real number can be represented in two forms: the first command converts the *decimal constant* into a form that can be used in a calc formula. The second form denotes the real number obtained by dividing the value of the first expression by the value of the second expression.

As an example, assume you want to scale a figure so that it occupies the full width of the page (`\textwidth`). If the original dimensions of the figure are given by the length variables `\Xsize` and `\Ysize`, then the height of the figure after scaling will be:

```
\setlength\newYsize{\Ysize*\ratio{\textwidth}{\Xsize}}
```

```
\widthof{material} \heightof{material} \depthof{material}
\totalheightof{material}
```

These four commands typeset *material* in a horizontal box, measure the result, and then return its width, height, depth, or totalheight (i.e., the sum of height and depth) as a length value, respectively. This can in turn be used in more complex calc expressions.

The `calc` package is used in a few examples in this book. If you do not want to apply it, you need to express the code given in the examples in the form of basic \LaTeX commands and sometimes even primitive \TeX constructs. Depending on what was used, this may be easy (these days) or still rather complicated.

For example, the setting of `\fcolwidth` on page 670 has to be translated from

```
\setlength\fcolwidth{#1-2\fboxsep-2\fboxrule}
```

and can today be expressed simply by using `\dimeval` from the L3 programming layer as follows:

```
\setlength\fcolwidth{\dimeval{#1-2\fboxsep-2\fboxrule}}
```

i.e., same syntax and only one additional command. Without `\dimeval` it gets worse, and we end with three fairly unreadable assignments:

```
\setlength\fcolwidth{#1}%  
\addtolength\fcolwidth{-2\fboxsep}%  
\addtolength\fcolwidth{-2\fboxrule}
```

Obviously the infix notation provided by `calc` is far more readable than the above, but today you can use in most situations `\dimeval`, `\skipeval`, `\inteval`, or `\fpeval`, which also offer infix notation and achieve similarly concise results. However, expressions involving, for example, `\ratio` or measurement commands such as `\widthof`, are not easily expressible without using `calc`, so it remains a useful extension.

A.5.3 `ifthen` — Advanced control structures

Sometimes you may want to typeset different material depending on the value of a logical expression. This is possible with the standard package `ifthen` (originally written by Leslie Lamport and reimplemented for $\text{\LaTeX} 2_{\epsilon}$ by David Carlisle), which defines commands for building control structures with \LaTeX . Because it is compatible with the syntax and approach used for \LaTeX 2.09, it has inherited a number of limitations; in particular, it is fragile depending on the tests used and so often does not work in moving arguments.

While fine for simple cases defined in the document preamble, it is not really advisable to use it for more complex coding in packages. There we recommend using the powerful functions of the L3 programming layer [115] instead.

```
\ifthenelse{test}{then-code}{else-code}
```

If the condition *test* is true, the commands in the *then-code* part are executed. Otherwise, the commands in the *else-code* part are executed.

A simple form of a condition is the comparison of two integers. For example, if you want to translate a counter value into English:

```
\usepackage{ifthen}
\newcommand\toEng[1]{\arabic{#1}\textsuperscript{%
\ifthenelse{\value{#1}=1}{st}{%
\ifthenelse{\value{#1}=2}{nd}{%
\ifthenelse{\value{#1}=3}{rd}{%
\ifthenelse{\value{#1}<20}{th}}}%
{\typeout{Value too high}}}}}}
```

This is the 5th section in the 1st appendix. This is the \toEng{section} section in the \toEng{chapter} appendix.

A-5-3

The following example defines a command to print the time in short form. It shows how complex operations (using the `calc` package) can be combined with conditional control statements.

```
\usepackage{csquotes,ifthen,calc}
\newcounter{hours}\newcounter{minutes}
\newcommand{\printtime}{\setcounter{hours}{\time/60}%
\setcounter{minutes}{\time-\value{hours}*60}%
\ifthenelse{\value{hours}<10}{0}{\thehours:%
\ifthenelse{\value{minutes}<10}{0}{\theminutes}}
```

The current time is “14:16”. The current time is \enquote{\printtime}.

A-5-4

```
\equal{string1}{string2}
```

The `\equal` command evaluates to *true* if the two strings *string1* and *string2* are equal after they have been completely expanded. You should be careful when using fragile commands in the strings; they need protection with the `\protect` command.

```
\usepackage{ifthen,shortvrb} \MakeShortVerb\|
\newcommand\BB{\CC}\newcommand\CC{\DD}
\newcommand\DD{AA} \newcommand\EE{EE}
\BB=\EE? False.      |\BB|=|\EE|?    \ifthenelse{\equal{\BB}{\EE}}{True}{False}.\par
\BB=\CC? True.      |\BB|=|\CC|?    \ifthenelse{\equal{\BB}{\CC}}{True}{False}.\par
\DD=\BB? True.      |\DD|=|\BB|?    \ifthenelse{\equal{\DD}{\BB}}{True}{False}.
```

A-5-5

```
\boolean{string}    \newboolean{string}    \setboolean{string}{value}
```

Basic T_EX knows about some switches that can have the value *true* or *false*.¹ To define your own switch, use `\newboolean` where *string* is a sequence of letters. This switch is initially set to *false*. To change its value, use `\setboolean` where the *value* argument is either the string *true* or *false*. You can then test the value by using `\boolean` in the first argument of `\ifthenelse`. It is also possible to test all

¹In the L^AT_EX kernel they are normally built using the more primitive `\newif` command.

<i>Boolean</i>	<i>Description</i>
<i>T_EX switches (can only be queried)</i>	
<code>hmode</code>	true, if typesetting is done in a horizontal direction (e.g., inside a paragraph or an LR box).
<code>vmode</code>	true, if typesetting is done vertically (e.g., if T _E X is between paragraphs).
<code>mmode</code>	true, if T _E X is typesetting a formula.
<i>L_AT_EX switches (read-only)</i>	
<code>@twoside</code>	true, if L _A T _E X is typesetting for double-sided printing.
<code>@twocolumn</code>	true, if L _A T _E X is typesetting in standard two-column mode (false inside multicols environments).
<code>@firstcolumn</code>	true, if @twocolumn is true and L _A T _E X is typesetting the first column.
<code>@newlist</code>	true, if L _A T _E X is at the beginning of a list environment (set to false when text after the first \item command is encountered).
<code>@inlabel</code>	true, after an \item command until the text following it is encountered.
<code>@noskipsec</code>	true, after a run-in heading until the text following it is encountered.
<i>L_AT_EX switches (read-write)</i>	
<code>@afterindent</code>	Switch checked by command \@afterheading (usually used in headings) to prevent (if false) indentation of next paragraph.
<code>@tempswa</code>	Temporary switch used internally by many L _A T _E X commands to communicate with each other.

Table A.5: L_AT_EX's internal \boolean switches

such internal flags of L_AT_EX with this command (the most common ones are shown in Table A.5). An example could be a test to see whether a document is using a one- or two-sided layout.

A-5-6	Two-sided printing.	<code>\usepackage{ifthen}</code>	<code>\ifthenelse{\boolean{@twoside}}{Two-sided}{One-sided} printing.</code>
-------	---------------------	----------------------------------	--

Note that despite the similar names there is no relationship to \IfBooleanTF discussed in Section A.1.4 on page 632. That command can be used only to query the parsing results of commands defined with \NewDocumentCommand, etc.

\lengthtest{test}

To compare dimensions, use \lengthtest. In its *test* argument you can compare two dimensions (either explicit values like 20cm or names defined by \newlength) using one of the operators <, =, or >.

As an example, let us consider a figure characterized by its dimensions `\Xsize` and `\Ysize`. It should be made to fit into a rectangular area with dimensions `\Xarea` and `\Yarea`, but without changing the aspect ratio of the figure. The following code calculates the new dimensions of the figure (`\newX` and `\newY`). The trick is to first calculate and compare the aspect ratios of both the rectangle and the figure and then to use the result to obtain the magnification factor.

```
\newlength{\sizetmp}\newlength{\areatmp}
\setlength{\sizetmp}{1pt*\ratio{\Xsize}{\Ysize}}
\setlength{\areatmp}{1pt*\ratio{\Xarea}{\Yarea}}
\ifthenelse{\lengthtest{\sizetmp > \areatmp}}
  {\setlength{\newX}{\Xarea}\setlength{\newY}{\newX*\ratio{\Ysize}{\Xsize}}}
  {\setlength{\newY}{\Yarea}\setlength{\newX}{\newY*\ratio{\Xsize}{\Ysize}}}
```

`\isodd{number}`

With the `\isodd` command you can test whether a given *number* is odd. If, for example, the string generated by a `\pageref` command is a valid number (as it normally is), then you can use the command in the following way:

This is an even-numbered page.

6

This is an odd-numbered page.

7

```
\usepackage{ifthen} \newcounter{pl}
\newcommand\pcheck{\stepcounter{pl}\label{pl-\thep1}%
\ifthenelse{\isodd{\pageref{pl-\thep1}}}{odd}{even}}
This is an \pcheck-numbered page. \newpage
This is an \pcheck-numbered page.
```

A-5-7

The `\isodd` command is specially tailored to support the above application even though the result of `\pageref` might be undefined in the first L^AT_EX run. Note that you cannot omit the `\label` and `\pageref` and instead simply use `\thepage`. The reason is that pages are built asynchronously. As a consequence, your code might get evaluated while a page is being built, and afterwards L^AT_EX's output routine decides to move that bit of the text to the next page, making the evaluation invalid if `\thepage` were used.

`\whiledo{test}{do-clause}`

The `\whiledo` command is valuable for executing certain repetitive command sequences. The following simple example shows how the command works:

I should not talk during seminar (1). I should not talk during seminar (2). I should not talk during seminar (3). I should not talk during seminar (4).

```
\usepackage{ifthen} \newcounter{howoften}
\setcounter{howoften}{1}
\whiledo{\value{howoften}<5}{I should not talk
during seminar (\thehowoften).
\stepcounter{howoften}}
```

A-5-8

<code>\and</code>	<code>\or</code>	<code>\not</code>	<code>\(</code>	<code>\)</code>
-------------------	------------------	-------------------	-----------------	-----------------

Multiple conditions can be combined into logical expressions via the logical operators (`\or`, `\and`, and `\not`), using the commands `\(` and `\)` as parentheses. A simple example is seen below:

```
\usepackage{ifthen}
\newcommand{\QU}[2]{%
  \ifthenelse{\( \equal{#1}{ENG} \and \equal{#2}{yes} \)
    \or          \(\equal{#1}{FRE} \and \equal{#2}{oui} \)}%
    {'OK'}{'not OK'}}
```

A-5-9

You agree “OK” or don’t “not OK”.	You agree <code>\QU{ENG}{yes}</code> or don’t <code>\QU{ENG}{no}</code> . <code>\par</code>
D’accord “OK” ou pas “not OK”?	D’accord <code>\QU{FRE}{oui}</code> ou pas <code>\QU{FRE}{non}</code> ?

A.6 Package and class file structure

In this final section we discuss what commands are available for the authors of package or class files. Even if you do not intend to write your own package, this section will help you understand the structure and content of class and package files like `book` or `varioref` and thus help you to make better use of them. Furthermore, some of the commands for packages are sometimes also useful in the document preamble of a document.

The general structure of class and package files is identical and consists of the following parts:

- `<rollback information>`*
- `<identification>`*
- `<initial code>`*
- `<declaration of options>`*
- `<execution of options>`*
- `<package loading>`*
- `<main code>`*

All these parts are optional. We discuss the commands available in each of the individual parts below. Table A.6 on the following page gives a short overview.

A number of declarations discussed below expect a *date* as one of their arguments. Such dates can always be specified either as `YYYY/MM/DD` (traditional \LaTeX way and fairly readable in the author’s opinion) or in ISO notation, i.e., as `YYYY-MM-DD`.

A.6.1 The rollback part

This first part of a package or class file provides the necessary information to roll back the code to an earlier date or a specific release using the `latexrelease` package

Rollback part

`\DeclareRelease{version}{date}{file}`

Declares that the *version* from a specific *date* of a package or class is stored in some *file*

`\DeclareCurrentRelease{version}{date}`

Current version of the package or class

Identification part

`\NeedsTeXFormat{format}[release]`

Needs to run under *format* (LaTeX2_ε) with a release date not older than *release*

`\ProvidesClass{name}[release info]` or `\ProvidesPackage{name}[release info]`

Identifies class or package *name* and specifies *release information*

`\ProvidesFile{name}[release info]`

Identifies other file *name* (with extension) and specifies *release information*

Declaration and processing of options (classic style)

`\DeclareOption{option}{code}` or `\DeclareOption*{code}`

Declares *code* to be executed for *option*; starred form is for unknown options

`\PassOptionsToPackage{option-list}{package-name}`

Passes *option-list* to *package-name*

`\CurrentOption`

Refers to current option for use in `\DeclareOption*`

`\OptionNotUsed`

For use in `\DeclareOption*` if necessary

`\ExecuteOptions{option-list}`

Executes code for every option listed in *option-list*

`\ProcessOptions` or `\ProcessOptions*`

Processes specified options for current class or package; starred form obeys the specified order

Declaration and processing of options (key/value style)

`\DeclareKeys[family]{key list with properties}`

Declares *keys* and their scope

`\SetKeys[family]{key/value list}`

Sets *keys* to values

`\ProcessKeyOptions[family]`

Processes specified key/value options for current class/package including any global class options

`\DeclareUnknownKeyHandler[family]{code}`

Replace the default error handler for unknown keys in *family* by executing *code* instead

Package loading

`\RequirePackage[option-list]{package}[release]`

Loads *package* with given *option-list* and a release date not older than *release*

Table A.6: Commands for package and class files

or the second optional argument of `\usepackage` or `\documentclass`. See Section 2.5.5 on page 114 for a description of the general approach. If present, it consists of one or more `\DeclareRelease` declarations followed by exactly one `\DeclareCurrentRelease` declaration.

`\DeclareRelease{version}{date}{file}`

This declaration states that there is a release of this package or class that was made available on *date* and can be accessed as *version* (if this argument is not empty). The code for this release is stored in *file*.

If there are several declarations, then they have to be ordered by *date*, because in a rollback situation the processing stops the moment a suitable *date* is found, i.e., one that is older or equal to the requested date and the next declaration is newer than the requested date. If a search for a *version* is done, then the first line matching that is selected.

`\DeclareCurrentRelease{version}{date}`

This declaration describes the current release and therefore has no *file* argument. It can be given a *version* name, and it has to be given a *date*. This date should be the one when the release was first made publicly available. Because small changes and corrections are usually not tracked for use with rollback, a `\ProvidesPackage` line in the identification part often shows a later date.

As an example, the array package starts with the following declarations:

```
\DeclareRelease{}      {2016-10-06}{array-2016-10-06.sty}
\DeclareRelease{v2.4}{2020-02-10}{array-2020-02-10.sty}
\DeclareCurrentRelease{}{2020-10-01}

\ProvidesPackage{array}
[2021/04/20 v2.5e Tabular extension package (FMI)]
```

This means that the newest (main) release is from 2020-10-01 and some minor fixes got added since then (so that package date is 2021/04/20), and if you roll back to a date after October 2020, you always get the latest file (no rollback). If you request an earlier date, then either `array-2016-10-06.sty` or `array-2020-02-10.sty` is loaded (based on your requested date), and the latter file is also loaded if you explicitly ask for version v2.4.

If an earlier release is selected, then processing of the current file stops, and the remainder is not looked at. This means that the files holding the earlier releases need to be complete in themselves. Typically they are just copies of the main package or class file the way it was at that point in time.

A.6.2 The identification part

This part of a class or package file is used to define the nature of the file and may also state the L^AT_EX 2_ε distribution release minimally required.

`\ProvidesClass{name} [release information]`

A class file identifies itself with a `\ProvidesClass` command. The argument *name* corresponds to the name of the class as it is used in the mandatory argument of the `\documentclass` command (i.e., the file name without an extension). The optional argument *release information*, if present, should begin with a date in the form *YYYY/MM/DD* or *YYYY-MM-DD*, separated with a space from the version number or identification, followed optionally by some text describing the class. For example, the class report contains something like

```
\ProvidesClass{report}[2021/02/12 v1.4n Standard LaTeX document class]
```

In a document you can make use of the *release information* by specifying the date as a second optional argument to the `\documentclass` command as follows:

```
\documentclass[twocolumn]{report}[2021/02/12]
```

This enables L^AT_EX to check that the report class used has at least a release date of 2021/02/12 or is newer. If the class file is older, a warning is issued. Thus, if you make use of a new release of a class file and send your document to another site, the people there are automatically informed if their L^AT_EX distribution is out of date.

`\ProvidesPackage{name} [release information]`

This command identifies a package file. The structure is the same as for the `\ProvidesClass` command. Again, the date in the *release information* can be used in a second optional argument to `\usepackage` to ensure that an up-to-date version of the package file is loaded. For example:

```
\usepackage[german]{varioref}[2020/08/11]
```

`\ProvidesFile{file name} [release information]`

This command identifies any other type of file. For this reason *file name* must contain the full file name including the extension.

`\NeedsTeXFormat{format} [release]`

In addition to one of the above commands, the *identification* part usually contains a `\NeedsTeXFormat` declaration. The *format* must be the string `LaTeX2e`. If the

optional *release* argument is specified, it should contain the release date of the required $\text{\LaTeX} 2_{\epsilon}$ distribution in the form YYYY/MM/DD or YYYY-MM-DD. For example,

```
\NeedsTeXFormat{LaTeX2e}[2020/10/01]
```

would require at least the $\text{\LaTeX} 2_{\epsilon}$ release distributed on October 1, 2020. If this command is present, anyone who tries to use your code together with an older \LaTeX release receives a warning message that something might fail. A newer release date is accepted without a warning. For example, in 2020/10/01 the hook management was introduced in \LaTeX . Thus, if your class or package makes use of this, such a line ensures that the necessary code is present.

All four declarations are optional. Nevertheless, their use in distributed class and package files eases the maintenance of these files.

A.6.3 The initial code part

You can specify any valid \LaTeX code in the *⟨initial code⟩* part, including code that loads packages with the `\RequirePackage` command (see Section A.6.7) if their code is required in one of the option declarations. For example, you might want to load the `calc` package at this point, if you plan to use it later. However, normally this part is empty.

A.6.4 The declaration of options

In this part all options known to the package or class are declared using the `\DeclareOption` command. It is forbidden to load packages in this part. We describe here the standard option handling where options are simple strings that are either provided or not when the package or class is loaded but without any further structure.

Over the years a number of extension packages that provide a key/value syntax for package and class options, e.g., `keyval`, `kvdefinekeys`, `kvoptions`, or `kvsetkeys`, were developed. If any of them is used for option handling, then the commands in this part of the file are different, and you have to look at the corresponding package documentation for details.

However, these days \LaTeX and the L3 programming layer also offer a general mechanism for this task and the interfaces to use that are discussed in Section A.6.6 on page 700. For new packages we recommend using the methods described there. Here we describe the traditional method with “simple” options.

```
\DeclareOption{option}{code}
```

The argument *option* is the name of the option being declared, and *code* is the code that executes if this option is requested. For example, the paper size option `a4paper` normally has a definition of the following form:

```
\DeclareOption{a4paper}{\setlength\paperheight{297mm}%
\setlength\paperwidth{210mm}}
```

In principle, any action — from setting a flag to complex programming instructions — is possible in the *code* argument of `\DeclareOption`.

An important function for use in `\DeclareOption` is the command `\PassOptionsToPackage`. It can pass one or more options to some other package that is loaded later.

`\PassOptionsToPackage{option-list}{package-name}`

The argument *option-list* is a comma-separated list of options that should be passed to the package with name *package-name* when it is loaded in the *package loading* part.¹ Suppose, for example, that you want to define a class file that makes use of two packages, say, A and B, both supporting the option `infoshow`. To support such an option in the class file as well, you could declare

```
\DeclareOption{infoshow}{%
  \PassOptionsToPackage{infoshow}{A}%
  \PassOptionsToPackage{infoshow}{B}%
  {code to support infoshow in the class}}
```

If a package or class file is loaded with an option that it does not recognize, it issues an error (in the case of a package file) or silently ignores the option (in the case of a class file), assuming that it is a global option to be passed to other packages subsequently loaded with `\usepackage`. However, this behavior is not hardwired and can be modified using a `\DeclareOption*` declaration.

`\DeclareOption*{code}`

Command does
not act on global
options!

The argument *code* specifies the action to take if an unknown option is specified on the `\usepackage` or `\RequirePackage` command. Within this argument `\CurrentOption` refers to the name of the option in question. For example, to write a package that extends the functionality of some other package, you could use the following declaration:

```
\DeclareOption*{\PassOptionsToPackage{\CurrentOption}{xyz}}
```

This would pass all options not declared by your package to package `xyz`. If no `\DeclareOption*` declaration is given, the default action, described above, is used.

By combining `\DeclareOption*` with `\InputIfFileExists` (see below), you can even implement conditional option handling. For example, the following code tries to find files whose names are built up from the option name:

```
\DeclareOption*{\InputIfFileExists{g-\CurrentOption.xyz}{}%
  {\PackageWarning{somenam}{Option \CurrentOption\space
    not recognized}}}
```

¹It is the responsibility of the package writer to actually load such packages. L^AT_EX does not check that packages receiving options via `\PassOptionsToPackage` are actually loaded later.

If the file `g-option.xyz` can be found, it is loaded; otherwise, the option is ignored with a warning.

```
\OptionNotUsed
```

If your *code* for `\DeclareOption*` inside a class file is more complex (e.g., trying to handle some options but rejecting others as in the previous example), you might need to explicitly inform \LaTeX that the option was not accepted with the help of the `\OptionNotUsed` command. Otherwise, \LaTeX thinks that the option was used and does not produce a warning if the option is not picked up by a later package.

A.6.5 The execution of options

Two types of actions are normally carried out after all options are declared. You might want to set some defaults, such as the default paper size. Then the list of options specified needs to be examined, and the code for each such option needs to be executed.

```
\ExecuteOptions{option-list}
```

The `\ExecuteOptions` command executes the code for every option listed in *option-list* in the order specified. It is just a convenient shorthand to set up defaults by executing code specified earlier with a `\DeclareOption` command. For example, the standard class `book` issues something similar to

```
\ExecuteOptions{letterpaper,twoside,10pt}
```

to set up the defaults. You can also use `\ExecuteOptions` when declaring other options, such as a definition of an option that automatically implies others. The `\ExecuteOptions` command can be used only prior to executing the `\ProcessOptions` command because, as one of its last actions, the latter command reclaims all of the memory taken up by the code for the declared options.

```
\ProcessOptions
```

When the `\ProcessOptions` command is encountered, it examines the list of options specified for this class or package and executes the corresponding code. More precisely, when dealing with a package, the global options (as specified on the `\documentclass` command) and the directly specified options (the optional argument to the `\usepackage` or `\RequirePackage` command) are tested. For every option declared by the package, the corresponding code is executed. This execution occurs in the same order in which the options were specified by the `\DeclareOption` declarations in the package, not in the order in which they appear on the `\usepackage` command. Global options that are not recognized are

ignored. For all other unrecognized options the code specified by `\DeclareOption*` is executed or, if this declaration is missing, an error is issued.

Thus, packages that use only `\DeclareOption*` when declaring options do not act upon global options specified on the `\documentclass`, but rather accept only those that are explicitly given on the `\usepackage` or `\RequirePackage` declaration.

In the case of a class file, the action of `\ProcessOptions` is the same without the added complexity of the global options.

There is one potential problem when using `\ProcessOptions`: the command searches for a following star (even on subsequent lines) and thereby may incorrectly expand upcoming commands following it. To avoid this danger use `\relax` at the end to stop the search immediately and start the execution of the options.

Preventing
unwanted expansion

`\ProcessOptions*`

For some packages it may be more appropriate if they process their options in the order specified on the `\usepackage` command rather than using the order given through the sequence of `\DeclareOption` commands. For example, in the `babel` package, the last language option specified is supposed to determine the main document language. Such a package can execute the options in the order specified by using `\ProcessOptions*` instead of `\ProcessOptions`.

A.6.6 Declaring and using options with a key/value syntax

Since 2020 the L^AT_EX kernel offers built-in support for creating key-based options through the L3 programming layer module `l3keys` for packages that are implemented using this layer.

From the June 2022 release on, key-based options are also supported through a small number of CamelCase commands, if the L3 programming layer is not being used. This interface is simpler and exposes only the most common key types by default, but these cover the vast majority of typical package option uses. Package authors who wish to exploit the full power of `l3keys` to define keys using more sophisticated key types can do so but then have to switch to L3 programming layer syntax. Details of using `l3keys` are out of scope here: please refer to the L3 programming layer documentation [115].

Please also note that this CamelCase interface is an alternative interface to the option declarations discussed in the previous two sections — it makes little sense to try to use both in parallel in the same package or class, even though with some restrictions it can be made to work.

`\DeclareKeys[family]{key-declarations}`

Keys are created using the command `\DeclareKeys`, which itself takes a key-value list of key names. Each key created will have one or more *properties*, which define

how it acts, and each of these key/property pairs has a *value*. Properties start with a period; the available ones are:

- `.code` executes arbitrary code when the key is used. The code can refer with `#1` to the value assigned to the key;
- `.if` sets a TeX `\if...` switch, e.g., `@twoside`;
- `.notif` like `.if`, but sets a TeX `\if...` switch to its inverted value;
- `.store` stores a value in a macro;
- `.usage` defines whether the option can be given only when loading (use value `load`), in the preamble (value `preamble`), or has no limitation on scope (value `general`). Can be given in addition to one of the other properties.

For example, with

```
\DeclareKeys {
  draft.if      = @mypkg@draft      ,
  final.notif   = @mypkg@draft      ,
  name.store    = \mypkg@name       ,
  address.store = \mypkg@address    ,
  debug.code    = \typeout{Debugging set to #1}
               ...                  ,
  draft.usage   = preamble          ,
  name.usage    = load
}
```

we create five key options for the current package: `draft`, `final`, `name`, `address`, and `debug`. The options `draft` and `final` are Boolean switches: they will accept only the values `true` or `false`. In the example, they have a tight relationship: specifying `final=false` is equivalent to `draft=true` (or shorter `draft`). The options `name` and `address` both accept any input and simply store it in the specified macros. The `name` can be set only when loading the package, `draft` can be set there or in the preamble, and `address` and `debug` can even be changed in the middle of the document. How to do that is explained below.

The `.store` property checks if the command used for storage exists: if not, it is defined with empty content so that it can safely be used afterwards. *.store type options*

Similarly, `.if` and `.notif` check if the specified TeX switch exists, i.e., in our example if `\if@mypkg@draft` is defined; and if not, they call `\newif` to declare it. *.if and .notif type options*

The option `debug` executes the code when the key is used; i.e., in the example it does a `\typeout`, displaying the value given to the key, and then executes some further code (indicated by `...`) to set up or alter the debugging. This is similar to `\DeclareOption` in the classic interface, except that your code can make use of the value given to the key. *.code type options*

Setting default
values for keys

If you want to set explicit default values for some or all of your keys declared with `\DeclareKeys`, use `\SetKeys` afterwards.

To ensure that keys of different packages can safely coexist, all keys declared with `\DeclareKeys` are divided up into *families*, with the requirement that the combination of *family*+*key* is unique across all keys ever declared. Within a package or class file, the *family* defaults to the name of the current file without extension (internally called `\@currname`), which means that every such package or class has its own name space by default.¹ If necessary, you can specify keys for other name spaces by using an explicit *family* argument, though that is seldom needed.

```
\DeclareUnknownKeyHandler[family]{code}
```

By default, keys unknown to the system raise an error if they are encountered during load or set with `\SetKeys`. In some situations that is not desirable, e.g., when a package wants to pass on unknown keys to some other package. In the classic interface that is handled through a `\DeclareOption*` declaration, but with key/value options there is the additional complexity of handling the given value and the fact that keys are structured by *family*.

`\DeclareUnknownKeyHandler` installs a new handler for keys of a given *family* replacing the default error handler otherwise used. The *code* receives the unknown key name as #1 and the value as #2. If no value was given, #2 is empty. These can then be processed as appropriate, e.g., by forwarding to another package.

Executing package or class options using a key/value syntax

If you use the key/value interface for options, then the processing of the options, given to the package or class, is carried out by the command `\ProcessKeyOptions` and not with the commands discussed in the previous section.

```
\ProcessKeyOptions[family]
```

The command takes the option list given to the package or class but expects it to consist of key/value pairs and processes them accordingly. In the case of a package, it also examines the global (class) options. It is normally used without the optional *family* argument, but if one was supplied to `\DeclareKeys`, then it is also needed here.

Unlike “classical” L^AT_EX package options, key-based options remain available to be set after `\ProcessKeyOptions` has been used. In particular, any such key can be used for more general settings in the document body. The scope that keys are live in is set by the `.usage` property, which can restrict a key to load-time only, to load-time and the document preamble, or to allow general scope.

No option
clash errors

Unlike “classical” options, L^AT_EX will not issue an option-clash warning when a package using `\ProcessKeyOptions` is loaded for a second time with (different) options. Instead, after the first loading, second and subsequent loading attempts

¹This is not quite true: you can have a class and a package use the same base name and thus have the same default name space. In that case you may have to set the *family* explicitly.

simply pass the option list to `\SetKeys`. This means that it is up to the package author to decide how to handle repeated option setting. Typically, those that can be given only once will be set as `.usage=load`.

It is possible to use `\DeclareKeys` declarations after the package-supplied option list has been processed, but keys defined by it can then obviously only be altered in the preamble or in the document body, but do not act as package options.

Declaring keys that do not serve as package options

```
\SetKeys[family]{key/value list}
```

Changing key values is achieved with the `\SetKeys` command: it requires a *key/value list* as its argument. For example, based on the example above

```
\SetKeys{address = {My place, My Town}}
```

would be valid within the package code after the `\DeclareKeys` line.

Outside the package, e.g., in the preamble or the document body, we would additionally need to provide an appropriate value for the optional *family* argument to change the key value. This is usually the package or class file name, but can be any name explicitly supplied as *family* to `\DeclareKeys` earlier.

Many packages offer dedicated configuration commands accepting key/value lists, e.g., `\geometry`, `\microtypesetup`, or `\SetupDoc`, to name a few. The naming conventions are quite diverse unfortunately. With the new interface it could be as simple as `\SetKeys[package]{key/value list}`. For backwards compatibility, a package switching over to the new system could still provide its old interface through a simple mapping, e.g., `\newcommand\geometry{\SetKeys[geometry]}`.

Standardizing the configuration interfaces

A.6.7 The package loading part

Once the options are dealt with, it might be time to load one or more additional packages — for example, those to which you have passed options to using the command `\PassOptionsToPackage`.

```
\RequirePackage[option-list]{package}[release]
```

This command is the package/class counterpart to the document command `\usepackage`. If *package* was not loaded before, it is loaded now with the options specified in *option-list*, the global options from the `\documentclass` command, and all options passed to this package via `\PassOptionsToPackage`.

\LaTeX loads a package only once because in many cases it is dangerous to execute the code of a package several times. Thus, if you require a package with a certain set of options, but this package was previously loaded with a different set not including all options requested at this time, then the user of your package has a problem. In this situation \LaTeX may¹ issue an error message informing users of your package

¹If the package uses key/value options, it depends on the properties of the keys whether a second loading attempt is possible; see the discussion on page 701.

about the conflict and suggesting that they load the package with a `\usepackage` command and all necessary options.

The optional *release* argument can be used to request a package version not older than a certain date. For this scheme to work, the required package must contain a `\ProvidesPackage` declaration specifying a release date.

It can also be used to request a specific named version `[=<version>]` or a version current at a certain date by using `[=<date>]` in the *release* argument. However, this should normally be avoided within packages or classes, because you force L^AT_EX to always load old and possible obsolete code.¹

```
\RequirePackageWithOptions{package}[release]
```

This command works like `\RequirePackage` except that the options passed to it are exactly those specified for the calling package or class. This facilitates the generation of variant packages that take exactly the same set of options as the original. See also the discussion of `\LoadClassWithOptions` on page 709.

A.6.8 The main code part

This final part of the file defines the characteristics and implements the functions provided by the given class or package. It can contain any valid L^AT_EX construct and usually defines new commands and structures. It is good style to use standard L^AT_EX commands, as described in this appendix, such as `\newlength`, `\newcommand`, `\NewDocumentCommand`, `\NewDocumentEnvironment`, and so on, rather than relying on primitive T_EX commands, because the latter do not test for possible conflicts with other packages.

A.6.9 Special commands for package and class files

With a few exceptions, the commands in this section are not useful outside a package or a document class.

```
\AtEndOfPackage{code}    \AtEndOfClass{code}
```

Sometimes it is necessary to defer the execution of some code to the end of the current package or class file. The above declarations save the *code* argument and execute it when the end of the package or class is reached. If more than one such declaration is present in a file, the *code* is accumulated and finally executed in the order in which the declarations were given.

These declarations are merely for convenience and help structure the code. Instead of using them, you can certainly place the necessary code at the very end of the package or class.

¹This facility is mainly intended for end users who need to reprocess an old document written when an earlier package version was the “current” one.

<i>Special commands for package and class files</i>	
<code>\AtEndOfPackage{code}</code>	<code>\AtEndOfClass{code}</code>
Defers execution of <i>code</i> to end of current package or class	
<code>\AtBeginDocument{code}</code>	<code>\AtEndDocument{code}</code>
Executes <i>code</i> at <code>\begin{document}</code> or <code>\end{document}</code>	
<code>\IfFileExists{file}{then-code}{else-code}</code>	
Executes <i>then-code</i> if <i>file</i> exists, <i>else-code</i> otherwise	
<code>\InputIfFileExists{file}{then-code}{else-code}</code>	
If <i>file</i> exists, executes <i>then-code</i> and then inputs <i>file</i> ; otherwise executes <i>else-code</i>	

<i>Special class file commands</i>	
<code>\LoadClass[option-list]{class}[release]</code>	
Like <code>\RequirePackage</code> for class files, but does not see global options if not explicitly passed to it	
<code>\PassOptionsToClass[option-list]{class}</code>	
Passes <i>option-list</i> to <i>class</i>	

Table A.7: Special commands for package and class files

<code>\AtBeginDocument{code}</code>	<code>\AtEndDocument{code}</code>
-------------------------------------	-----------------------------------

Other important points at which you might want to execute deferred code are the beginning and the end of the document or, more exactly, the points where the `\begin{document}` and `\end{document}` are processed. The above commands allow packages to add code to this environment without creating any conflicts with other packages trying to do the same. Note, however, that code in the `\AtBeginDocument` hook is part of the preamble. Thus, restrictions limit what can be put there; in particular, no typesetting can be done.

These days the commands are implemented using the hook management system of \LaTeX described in Section A.4; e.g., `\AtBeginDocument{code}` is just an abbreviation for

```
\AddToHook{begindocument}[package-or-class-name]{code}
```

and there are further hooks into `\begin{document}` that allow for even more granular control. For example, `begindocument/after` can be used to add typesetting material at the very beginning of the document body.

<code>\IfFileExists{file}{then-code}{else-code}</code>
<code>\InputIfFileExists{file}{then-code}{else-code}</code>

If your package or class tries to `\input` a file that does not exist, the user ends up in \TeX 's file-error loop. It can be exited only by supplying a valid file name. Your package or class can avoid this problem by using `\IfFileExists`. The argument

file is the file whose existence you want to check. If this *file* is found by L^AT_EX, the commands in *then-code* are executed; otherwise, those in *else-code* are executed. The command `\InputIfFileExists` tests not only whether *file* exists, but also inputs it immediately after executing *then-code*. The name *file* is then added to the list of files to be displayed by `\listfiles`.

```
\PackageWarning{name}{text}      \PackageWarningNoLine{name}{text}
\PackageNote{name}{text}         \PackageNoteNoLine{name}{text}
\PackageInfo{name}{text}
```

When a package detects a problem, it can alert the user by printing a warning message on the terminal. For example, when the `multicol` package detects that `multicols*` (which normally generates unbalanced columns) is used inside a box, it issues the following warning:¹

```
\PackageWarning{multicol}{multicols* inside a box does
not make sense.\MessageBreak  Going to balance anyway}
```

This produces a warning message, which is explicitly broken into two lines via the `\MessageBreak` command:

```
Package multicol Warning: multicols* inside a box does not make sense.
(multicol)                Going to balance anyway on input line 6.
```

The current line number is automatically appended. Sometimes it would be nice to display the current file name as well, but unfortunately this information is not available on the macro level.

Depending on the nature of the problem, it might be important to tell the user the source line on which the problem was encountered. In other cases this information is irrelevant or even misleading, such as when the problem happens while the package is being loaded. In this situation, `\PackageWarningNoLine` should be used; it produces the same result as `\PackageWarning` but omits the phrase “on input line *number*”.

If the information is not really a warning, but just something you want the user to be informed about, you can use `\PackageNote` or `\PackageNoteNoLine`; both produce the same kind of output, but with `Warning` replaced by `Info`.

If this information should appear just in the transcript file, then one can use `\PackageInfo`. For example, after loading the `shortvrb` package and issuing the declaration `\MakeShortVerb\=`, the transcript file shows the following:

```
Package shortvrb Info: Made = a short reference for
\verb on input line 3.
```

¹In a box, balancing is essential because a box can grow arbitrarily in vertical direction, so all material would otherwise end up in the first column.

A `\PackageInfoNoLine` command is not provided. If you really want to suppress the line number in an informational message, use `\@gobble` as the last token in the second argument of `\PackageInfo`.

$$\backslash\text{PackageError}\{name\}\{short\text{-}text\}\{long\text{-}text\}$$

If the problem detected is severe enough to require user intervention, one can signal an error instead of a warning. If the error is encountered, the *short-text* is displayed immediately and processing stops. For example, if `inputenc` encounters an 8-bit character it does not recognize, it produces the following error:

```
! Package inputenc Error: Keyboard character used is undefined
(inputenc)                in inputencoding 'latin1'.
```

```
See the inputenc package documentation for explanation.
Type H <return> for immediate help.
...
```

```
1.5 abc^^G
?
```

If the user then presses “h” or “H”, the *long-text* is offered. In this case it is:

```
You need to provide a definition with \DeclareInputText
or \DeclareInputMath before using this key.
```

As before, you can explicitly determine the line breaks in the error and help texts by using `\MessageBreak`.

$\backslash\text{ClassWarning}\{name\}\{text\}$	$\backslash\text{ClassWarningNoLine}\{name\}\{text\}$
$\backslash\text{ClassNote}\{name\}\{text\}$	$\backslash\text{ClassNoteNoLine}\{name\}\{text\}$
$\backslash\text{ClassInfo}\{name\}\{text\}$	$\backslash\text{ClassError}\{name\}\{short\text{-}text\}\{long\text{-}text\}$

Information, warning, and error commands are not only available for packages — similar commands are provided for document classes. They differ only in the produced texts: the latter commands print “Class” instead of “Package” in the appropriate places.

$$\begin{array}{l} \backslash\text{IfFormatAtLeastTF}\{date\}\{true\text{-}code\}\{false\text{-}code\} \\ \backslash\text{IfPackageAtLeastTF}\{package\}\{date\}\{true\text{-}code\}\{false\text{-}code\} \\ \backslash\text{IfClassAtLeastTF}\{package\}\{date\}\{true\text{-}code\}\{false\text{-}code\} \end{array}$$

Sometimes it is important to ensure that the \LaTeX kernel or a certain package or class is from a specific date (or later), because that decides what code to execute. For example, commands such as `\NewDocumentCommand`, described in Section A.1.4, were added to \LaTeX in 2020-10-01 and therefore cannot be used in a package running on top of an earlier distribution. That can be solved by requiring a recent enough kernel using `\NeedsTeXFormat`. However, as a package author you may want to

support older distributions, and in that case this could be done by loading `xparse`, i.e.,

```
\IfFormatAtLeastTF{2020-10-01}{\RequirePackage{xparse}}
```

In the same way, adjustments for specific package versions (`\IfPackageAtLeastTF`) or class versions (`\IfClassAtLeastTF`) can be made.

```
\IfPackageLoadedTF{package}{true-code}{false-code}
\IfPackageLoadedWithOptionsTF{package}{options}{true-code}{false-code}
```

Sometimes it is useful to be able to find out if a package is already loaded, and if so, how. For this purpose, two commands are made available to class (and package) writers. To find out if a *package* has already been loaded, use `\IfPackageLoadedTF`. To find out if a *package* has been loaded with at least the (comma-separated) *options* list, use `\IfPackageLoadedWithOptionsTF`.

Note that the `fontenc` package cannot be tested with the above commands. That's because it pretends that it was never loaded to allow for repeated reloading with different options (see the file `ltoutenc.dtx` in the L^AT_EX distribution for details).

Testing for classes can be done with the commands `\IfClassLoadedTF` and `\IfClassLoadedWithOptionsTF`. They can, for example, be used to define commands that behave differently if used with different document classes.

A.6.10 Special commands for class files

It is sometimes helpful to build a class file as a customization of a given general class. To support this concept two commands are provided.

```
\LoadClass[option-list]{class}[release]
```

The `\LoadClass` command works like the `\RequirePackage` command with the following three exceptions:

- The command can be used only in class files.
- There can be at most one `\LoadClass` command per class.
- The global options are not seen by the *class* unless explicitly passed to it via `\PassOptionsToClass` or specified in the *option-list*.

```
\PassOptionsToClass{option-list}{class}
```

The command `\PassOptionsToClass` can be used to pass options to such a general class. An example of such a class file augmentation is shown in Figure A.1 on the next page. It defines a class file `myart` that accepts two extra options, `cropmarks` (making crop marks for trimming the pages) and `bind` (shifting the printed pages slightly to

```

% ----- identification -----
\NeedsTeXFormat{LaTeX2e}
\ProvidesClass{myart}[2021/01/01]
% ----- initial code -----
\RequirePackage{ifthen}      \newboolean{cropmarks}
% ----- declaration of options --
\DeclareOption{cropmarks}{\setboolean{cropmarks}{true}}
\DeclareOption{bind}        {\AtEndOfClass{\addtolength\oddsidemargin{.5in}%
                                     \addtolength\evensidemargin{-.5in}}}
\DeclareOption*              {\PassOptionsToClass{\CurrentOption}{article}}
% ----- execution of options -----
\ProcessOptions \relax      % cf. hint on p.700!
% ----- package loading -----
\LoadClass{article}         % the real code
% ----- main code -----
\newenvironment{Notes}{...}{...} % the new environment
\ifthenelse{\boolean{cropmarks}} % support for cropmarks
  {\renewcommand{\ps@plain}{...} ...}{...}

```

Figure A.1: An example of a class file extending article

the outside to get a larger binding margin), as well as one additional environment, `Notes`.

The `cropmarks` option is implemented by setting a Boolean switch and redefining various `\pagestyles` if this switch is true. The `bind` option modifies the values of `\oddsidemargin` and `\evensidemargin`. These length registers do not have their final values at the time the `bind` option is encountered (they are set later, when the article class is loaded by `\LoadClass`), so the modification is deferred until the end of the `myart` class file using the `\AtEndOfClass` command.

`\LoadClassWithOptions{class}[release]`

This command is similar to `\LoadClass`, but it always calls the `class` with exactly the same option list that is being used by the current class, rather than the options explicitly supplied or passed on by `\PassOptionsToClass`. It is mainly intended to allow one class to build on another. For example:

```
\LoadClassWithOptions{article}
```

This should be contrasted with the following slightly different construction:

```

\DeclareOption*{\PassOptionsToClass{\CurrentOption}{article}}
\ProcessOptions \LoadClass{article}

```

As used here, the effects are more or less the same, but the version using the command `\LoadClassWithOptions` is slightly quicker (and less onerous to type). If,

however, the class declares options of its own, then the two constructions are different. Compare, for example,

```
\DeclareOption{landscape}{...}
\ProcessOptions                \LoadClassWithOptions{article}
```

with:

```
\DeclareOption{landscape}{...}
\DeclareOption*{\PassOptionsToClass{\CurrentOption}{article}}
\ProcessOptions                \LoadClass{article}
```

In the first example, the article class is called with the option `landscape` only when the current class is called with this option. In the second example, however, the option `landscape` is never passed to the article class, because the default option handler passes only options that are *not* explicitly declared.

A.6.11 A minimal class file

Every class file *must* contain at least four things: a definition of `\normalsize`, values for `\textwidth` and `\textheight`, and a specification for page numbering. Thus, a minimal document class file¹ could look like this:

```
\NeedsTeXFormat{LaTeX2e}
\ProvidesClass{minimal}[2001/05/25 Standard LaTeX minimal class]
\renewcommand\normalsize{\fontsize{10pt}{12pt}\selectfont}
\setlength\textwidth{6.5in}
\setlength\textheight{8in}
\pagenumbering{arabic}          % needed even though this class does
                                %   not show page numbers
\pagestyle{empty}              % this is actually already in the kernel
```

This class file does not support footnotes, marginals, floats, or other features. Naturally, most classes contain more than this minimum!

¹This class is in the standard distribution, as `minimal.cls`. It is not very useful, though—not even for producing bug reports; it is better use the article class for that.

Tracing and Resolving Problems

B.1 Error messages	712
B.2 Dying with memory exceeded	744
B.3 Warnings and informational messages	749
B.4 T _E X and L ^A T _E X commands for tracing	765

In an ideal world all documents you produced would compile without problems and give high-quality output as intended. If you are that lucky, there will be no need for you to consult this appendix, ever. However, if you run into a problem of some kind, the material in this appendix should help you to resolve your problem easily.

We start with an alphabetical list of all error messages, those after which L^AT_EX stops and asks for advice. “All” in this context means all L^AT_EX kernel errors (their text starts with `LaTeX Error:` or `LaTeX <module> Error`), practically all T_EX errors (i.e., those directly produced by the underlying engine), and errors from the packages `amsmath`, `babel`, `calc`, `color`, `fontenc`, `graphics`, `graphicx`, and `inputenc`. Errors reported by other packages — those that identify themselves as

`! Package <package> Error: <error text>`

where `<package>` is not one of the above — are not included. For such errors you should refer to the package description elsewhere in the book or consult the original package documentation.

But even if there are no real errors that stop the processing, warning and information messages might be shown on the terminal or in the transcript file. They are treated in Section B.3, where you will find all L^AT_EX core messages and all relevant T_EX messages that may need your attention, together with an explanation of their possible causes and suggestions on how to deal with them.

The final section deals with tools for tracing problems in case the error or warning information itself is not sufficient or does not exist. We will explore ways to display command definitions and register values and then take a look at diagnosing and solving page-breaking problems. This is followed by suggestions for identifying and solving paragraph-breaking problems and includes a brief look at two LuaTeX-only packages for dealing with hyphenation issues. We finish with a description of the trace package, which helps in thoroughly tracing command execution, if your own definitions or those of others produce unexpected results.

Some of the material in this appendix can be considered “low-level” TeX, something that, to the author’s knowledge, has never been described in any other L^AT_EX book. It is, however, often important information. Directing the reader to books like *The TeXbook* does not really help, because most of the advice given in books about plain TeX is not applicable to L^AT_EX or produces subtle errors when used. We therefore try to be as self-contained as possible by offering all relevant information about the underlying TeX engine as far as it makes sense within the L^AT_EX context.

B.1 Error messages

When L^AT_EX stops to display an error message, it also shows a line number indicating how far it got in the document source. However, because of memory considerations in the design of TeX itself, it does not directly show to which file this source line number belongs. For simple documents this is not a problem, but if your document is split over many files, you may have to carefully look at the terminal output or the transcript file to identify the file L^AT_EX is currently working on when the error occurs.¹

*Finding the source
line of an error*

Whenever L^AT_EX starts reading a file, it displays a “(” character that is immediately followed by the file name. Once L^AT_EX has finished reading the file, it displays the matching “)” character. In addition, whenever it starts preparing to output a page, it displays a “[” character followed by the current page number. Thus, if you see something like

```
(./trial.tex [1] (./ch-1.tex [2] [3] (./table-1.tex [4] [5]) [6]
! Undefined control sequence.
<argument> A \textss
                {Test}
1.235 \section{A \textss{Test}}
                                \label{sec:test}

?
```

you can deduce that the error happened inside an argument of some command (<argument>) and was detected when L^AT_EX gathered material for page 7. It got as far as reading most of line 235 in the file `ch-1.tex`. In this example the error is readily

¹ A useful little helper for this is the `structuredlog` package. Once loaded, it uses the file hooks to identify the start and end of file-reading actions in the `.log` with lines such as “== (LEVEL 2 START) table-1.tex” and corresponding STOP lines. Thus, to find out where some error has occurred you only have to search backwards for the string “(LEVEL” and if that is a START line you are done; otherwise, you have to search further for the START line with the next lower level number.

visible in the source line: `\textsf` was misspelled as `\textss` inside the argument to the `\section` command. In some cases, however, the relationship between error and source line is blurred or even nonexistent.

For example, if you define `\renewcommand\thepart{\Alp{part}}`, then the typo appears only when you use the `\part` command that executes your definition. In that case you get

```
! Undefined control sequence.
\thepart ->\Alp
               {part}
1.167 \part{Test}
```

In this particular case the actual error is not on line 167 and most likely not even in the current file — the `\part` command merely happens to call the faulty definition of `\thepart`.

Sometimes an error is detected by \LaTeX while it is preparing a new page. Because this is an asynchronous operation, the source line listed in the error message is of no value whatsoever. So if you do not understand how the error should be related to the source line, you may well be right — there is, indeed, no relationship. Here is an example:

```
! Undefined control sequence.
\thepage ->\romen
               {page}
1.33 T
    his is a sample text to fill the page.
```

One way to obtain additional information about an error (or information about how \LaTeX intends to deal with it) is to press the key `h` in response to the `?` that follows the error message. If used with a \TeX error such as the one above, we get

```
? h
The control sequence at the end of the top line
of your error message was never \def'ed. If you have
misspelled it (e.g., '\hobx'), type 'I' and the correct
spelling (e.g., 'I\hbox'). Otherwise just continue,
and I'll forget about whatever was undefined.
```

You probably already see the problem with advice coming directly from the \TeX engine: you may have to translate it, because it often talks about commands that are not necessarily adequate for \LaTeX documents (e.g., for `\def` you should read `\newcommand` or `\NewDocumentCommand`). With real \LaTeX errors this is not the case, though here you sometimes get advice that is also not really helpful:

```
You're in trouble here. Try typing <return> to proceed.
If that doesn't work, type X <return> to quit.
```

Well, thank you very much; we already knew that! Typing `h` (*return*) is, however, worth a try, because there are many messages with more detailed advice.

*Displaying the stack
of partially
expanded macros*

Another way to get additional information about an encountered error is to set the counter `errorcontextlines` to a large positive value. In that case \LaTeX lists the stack of the current macro executions:

```

1  ! Undefined control sequence.
2  \thepage ->\romen
3      {page}
4  \@oddfoot ->\reset@font \hfil \thepage
5      \hfil
6  \@outputpage ...lor \hb@xt@ \textwidth {\@thefoot
7      } \color@endbox }} \globa...
8
9  \@opcol ...lumn \@outputdblcol \else \@outputpage
10     \fi \global \mparbotto...
11 <output> ...specialoutput \else \@makecol \@opcol
12     \startcolumn \@whiles...
13 <to be read again>
14     T
15 1.33 T
16     his is a sample text to fill the page.
```

You read this bottom up: \LaTeX has seen the T (lines 15 and 16) but wants to read it again later (<to be read again>, lines 13 and 14) because it switched to the output routine (<output>). There it got as far as executing the command `\@opcol` (lines 11 and 12), which in turn got as far as calling `\@outputpage` (lines 9 and 10), which was executing `\@thefoot` (lines 6 and 7). Line 4 is a bit curious because it refers to `\@oddfoot` rather than `\@thefoot` as one would expect (`\@thefoot` expands to `\@oddfoot`, so it is immediately fully expanded and not put onto the stack of partially expanded macros). Inside `\@oddfoot` we got as far as calling `\thepage`, which in turn expanded to `\romen` (lines 2 and 3), which is finally flagged as an undefined command (line 1).

Fortunately, in most cases it is sufficient only to display the error message and the source line. This is why \LaTeX 's default value for `errorcontextlines` is -1, which means not showing any intermediate context.

Error 
during expansion

Errors can occur when \LaTeX is doing expansions rather than typesetting. This is a problematical time, because in that mode \TeX is not able to do any assignments, which is a prerequisite to display \LaTeX error or warning messages with useful help texts. It is also difficult to stop the expansion in time when an error condition is identified without stopping it when there is no error condition. Nevertheless, with some gymnastics it is possible to produce reasonable error messages (as long as you ignore the help text that you get by typing `h` in response to the error). The trick used by \LaTeX is to produce a low-level \TeX error, but to do this in a way that it nearly looks like a normal \LaTeX error.

```

! Use of \??? doesn't match its definition.
<argument> \???
! LaTeX cmd Error: Required argument missing for \foo.
1. ... }
```

The artificially generated low-level \TeX error to stop the expansion is responsible for the first line of the error, i.e., “! Use of \??? doesn’t match its definition”. It is always the same line in such error messages — and no, nobody has defined a command with the name \???, but it is not unreasonable to think of it as a placeholder for *the current command* that has a problem.

The interesting part is the line starting with “! LaTeX (type) Error: \langle reason \rangle ” that you can look up in this appendix. The help text, on the other hand (that you get by using `h`), is not helpful, because it gives an explanation of the low-level error that \LaTeX had artificially produced:

```
If you say, e.g., ‘\def\al{...}’, then you must always
put ‘1’ after ‘\a’, since control sequence names are
made up of letters only. The macro here has not been
followed by the required stuff, so I’m ignoring it.
```

Thus, if you see a “! Use of \??? doesn’t match ...” error and you do not understand what it means, come straight to this appendix and look up the \langle reason \rangle given on the third line.

Errors can also occur when \LaTeX is processing an intermediate file used to transfer information between two runs (e.g., `.aux` or `.toc` files). Data in such files can be corrupted due to an error that happened in a previous run. Even if you have corrected that error in your source, traces of it may still be present in such external files. Therefore, in some cases you may have to delete those files before running \LaTeX again, although often the problem vanishes after another run.

 Persistent errors

Common sources for such nasty errors in \LaTeX are so-called *fragile* commands used unprotected in *moving arguments*. Technically, a moving argument is an argument that is internally expanded by \LaTeX without typesetting it directly (e.g., by using the internal \LaTeX construct `\protected@edef1`). But as a rule of thumb you can think of it as an argument that is moved somewhere else before typesetting — for example, the arguments of sectioning commands, such as `\section` (sent to the table of contents), the argument of `\caption` (sent to the list of figures or tables), and the arguments of `\markboth` and `\markright`.

 Errors due to fragile commands

The best, though not very helpful, definition of a fragile command is that it is a command that produces errors if it is not preceded with a `\protect` command when used in a moving argument.

Commands that are not fragile either have an expansion that is harmless in a moving argument (for example, they expand to simple text characters) or they have been explicitly made *robust*, which means they do not expand at all in such arguments. Today, most common \LaTeX commands have been made robust (i.e., nonexpanding) so that such protection is seldom necessary. However, if you get strange errors from a command used in a moving argument, try preceding it with `\protect`.

 Robust commands do not expand in moving arguments

¹ Some people have heard that the \TeX primitive `\edef` exists for this purpose. It is not advisable to use it in your own commands, however, unless you know that it will never receive arbitrary document input. You should use `\protected@edef` instead, because that command prevents fragile commands from breaking apart if they are prefixed by `\protect`!

There are no precise rules defining which commands belong to which category. User-defined commands made with `\NewDocumentCommand` are generally robust, but simple commands defined with `\newcommand` and with only mandatory arguments are fragile if they contain any fragile commands in their definition. For example, the definition

```
\newcommand\frail{\ifthenelse{\value{section}<10 \and
                             \value{subsection}=1}%
                             {\typeout{Yes}}{\typeout{No}}}
```

is fragile because the comparison argument of `\ifthenelse` is fragile. If you used `\frail` in the `@` expression of a `tabular` (not that this makes much sense),

```
\nonstopmode      \begin{tabular}{@{\frail}l} x \end{tabular}
```

you would see the following 101 errors before \LaTeX finally gives up (the left column displays the number of occurrences):

```
1 ! Argument of \@firstoftwo has an extra }.
1 ! Argument of \renew@command has an extra }.
1 ! Extra \or.
83 ! Illegal parameter number in definition of \reserved@a.
1 ! Paragraph ended before \@firstoftwo was complete.
1 ! Paragraph ended before \renew@command was complete.
4 ! Undefined control sequence.
8 ! Use of \@array doesn't match its definition.
1 ! ==> Fatal error occurred, no output PDF file produced!
```

*All \TeX errors
can be caused by
a fragile command
in a moving
argument!*

*Errors
produced by
cross-reference keys*

What we can learn from this example is the following: whenever you encounter a strange \TeX error that has no simple explanation (such as a misspelled command name), it is possibly due to a fragile command that got broken in a moving argument — so try protecting it with `\protect` at the point where the error occurs. Because this can be the reason behind every \TeX error, we shall not repeat this possible cause for every one of them (after all, more than 60 \TeX error messages are explained below).

As discussed in Section A.1.1, a few restrictions are placed on the characters that can be used in reference key arguments of `\label` and `\bibitem`. In a nutshell, such keys sometimes act like moving arguments and, depending on the combination characters used and the packages loaded, all kinds of dreadful \TeX errors may show up. In that case protection with using the `\protect` command does *not* work; instead, you have to use a simpler key conforming to the syntax restrictions for such keys.

Alphabetical listing of \TeX and \LaTeX errors

In the list of errors below, all \TeX and all package errors are flagged with a boxed reference at the end of the error message. Newer \LaTeX errors originating from a specific module are flagged with the module name in parentheses, while the older

L^AT_EX errors are unflagged. In all cases the typical prefix, e.g., “LaTeX *<module>* Error:” or “Package *<name>* Error:”, is omitted.

* T_EX

If L^AT_EX stops by just displaying a star, then it has reached the end of your source document without seeing a request to finish the job (i.e., `\end{document}` or `\stop`) and is now waiting for input from the terminal. While this is in itself not an error, in most circumstances it means that something went seriously wrong. If there have been no previous errors and your document finishes with `\end{document}`, then you might have forgotten to close a `verbatim` environment so that the remainder of the document was processed “verbatim”.

To find the source of this problem in a large document, reply `\end{foo}`, which either should give you an “Environment ... ended by...” error (indicating what environment L^AT_EX thinks is still open) or is swallowed without any reaction, in which case you know that you are indeed in some “verbatim” context. In the latter event, try to interrupt L^AT_EX (by pressing Control-C or whatever your installation requires) and reply with “x” to the “Interruption” error to quit the job. Looking afterwards at the last page in the typeset document usually gives some hint about where things started to go wrong.

‘*<character>*’ invalid at this point calc

You loaded the `calc` package, and one of the expressions in `\setcounter`, `\setlength`, `\addtocounter`, or `\addtolength` used a syntax not supported by `calc`. See Section A.5.2 for details.

<hex number> too large for Unicode

With `\DeclareUnicodeCharacter` you can only declare Unicode characters with a *<hex number>* of 110FFF or less; anything larger generates this error.

<command> allowed only in math mode amsmath

This command or environment can be used only in math mode. Check carefully to see what is missing from your document.

`\<` in mid line

The `\<`, defined within a `tabbing` environment, was encountered in the middle of a line. It can be used only at the beginning of a line (e.g., after `\<`).

A `<Box>` was supposed to be here T_EX

This error is the result of using a box command, such as `\sbox`, with an invalid first argument (i.e., one not declared with `\newsavebox`). Usually, you first get the error “Missing number, treated as zero” indicating that T_EX uses box register zero.

Argument delimiter ‘*<delimiter>*’ invalid in *<command or environment>* (cmd)

Some argument types available with `\NewDocumentCommand` or its siblings require you to specify delimiters. You get this error message if the specified delimiter is not a single nonblank token or if it is an implicit group token, such as `\bgroup`. Neither is supported.

Argument of `<command>` has an extra `}` TeX

A right brace was used in place of a mandatory command argument (e.g., `\mbox{}`). Fragile commands, when used without `\protect` in a moving argument, often break in a way that generates this or one of the other “extra” errors discussed below.

Argument type ‘b’ must be last in `<environment>` cmd

In a `\NewDocumentEnvironment` declaration you can use the type `b` to indicate the body of the environment. However, in this instance it is not the last argument specified, which it has to be, in order to grab the environment body.

Bad argument specification ‘`<spec>`’ of `<command or environment>` cmd

The argument specification of a command defined with `\NewDocumentCommand` or an environment defined with `\NewDocumentEnvironment` has a problem. Possible causes are:

- Some parts of the specification are missing required components; e.g., a `D` specifier needs to be followed by two delimiters and a default value;
- The final argument of an expandable command, i.e., one defined with a `\NewExpandableDocumentCommand` declaration, cannot be optional.

Bad `\line` or `\vector` argument

TeX issues this error if you specified a negative length or used an illegal slope with either `\line` or `\vector`. In the latter case, see Chapter 8 for alternatives.

Bad math environment delimiter

This error is triggered when a `\(` or `\[` command is encountered inside a formula or when `\)` or `\]` is found in normal text. Check whether these commands are properly matched in your document.

`\begin{<env>}` allowed only in paragraph mode amsmath

There are many places, such as within LR-mode text or math mode, where it does not make sense to have a math display. With `amsmath` the whole display `<env>` is simply ignored.

`\begin{<env>}` on input line `<line number>` ended by `\end{<other env>}`

You receive this error when TeX detects that the environment `<env>` was incorrectly terminated with the end-tag for the environment `<other env>`. The most likely case is that you, indeed, forgot to close the environment `<env>`.

Another possible source of this error is trying to use verbatim-like environments or an `amsmath` display environment inside the definition of your own environments, which is often impossible. See Section 4.2.4 on page 1317 for solutions involving verbatim-like environments.

If neither is the case and you are absolutely sure that all environments are properly nested, then somewhere between the start of `<env>` and the point where the error was found there must be a command that issues an `\endgroup` without a prior matching `\begingroup` so that TeX is fooled into believing that the

`<env>` environment ended at this point. One way to find that problem is to move the end-tag closer to the begin-tag, until the problem disappears.

`\begin{split}` won't work here amsmath

Either this `split` environment is not within an equation or perhaps you need to use `aligned` here.

Can be used only in preamble

\TeX has encountered a command or environment that should be used only inside a package or the preamble (i.e., before `\begin{document}`). This error can also be caused by a second `\begin{document}`.

Cannot add code to disabled hook '`<hook>`' (hooks)

Generic command hooks, e.g., `cmd/<cmd>/after`, do not work for all `<cmd>`s (in particular the `/after` hooks). To avoid unpleasant surprises they can therefore be explicitly disabled in which case `\AddToHook` does not accept them and instead replies with this error message.

Cannot define non-active Unicode char value `< 00A0`

Unicode character values less than `00A0` (decimal 160) can normally not be used with `\DeclareUnicodeCharacter` to give them a special LICR interpretation in pdf \TeX . Exceptions are a few characters that have been made active by \TeX .

Cannot determine size of graphic in `<file>` graphics|graphicx

You did not specify an explicit image size on the `\includegraphics` command, and \TeX was unable to determine the image size from the graphics `<file>` directly. It usually does this automatically, for example, for `.eps` files by reading the bounding box information. However, depending on the graphics driver, it may be unable to extract this information from binary bitmap images such as `.jpg` or `.png` files.

Cannot include graphics of type: `<ext>` graphics|graphicx

You get this error if you have specified a graphics type in the second argument of `\DeclareGraphicsRule` or used the `type` keyword of `\includegraphics`, for which the loaded graphics driver has no support.

Cannot remove chunk '`<label>`' from hook '`<hook>`' because `<reason>` (hooks)

You tried to remove a chunk of code labeled `<label>` using `\RemoveFromHook`, but either the `<hook>` does not exist or there is no such chunk. You can look at the hook with `\ShowHook` to verify that there is no spelling mistake.

Circular dependency in defaults of `<name>` (cmd)

Optional arguments in `\NewDocumentCommand` or its variants can have defaults that use the content of other arguments in their default value. If you go overboard with that approach, you may end up with a circular dependency that \TeX is unable to resolve for you, and in that case you get this error message.

`\caption` outside float

A `\caption` command was found outside a float environment, such as a figure

or table. This error message is disabled by some of the extension packages described in Chapter 7.

Command $\langle name \rangle$ already defined

You try to declare a command, an environment, a new savebox, a length, or a counter with a $\langle name \rangle$ that already has a meaning in \LaTeX . Your declaration is ignored, and you have to choose a different name. This error is also triggered if you use $\backslash newcommand$ with a $\langle name \rangle$ starting in $\backslash end. . .$, even if $\backslash renewcommand$ claims the $\langle name \rangle$ is unused. It is also issued if you try to define an environment $\langle name \rangle$ but the command $\backslash end\langle name \rangle$ already has a definition. For instance, you cannot define an environment `graf` because \TeX has a low-level command called $\backslash endgraf$.

Command $\langle name \rangle$ invalid in math mode

This is either a warning or an error message indicating that you have used a command in math mode that should be used only in normal text. In the case of an error message, use `h` to get further help.

Command $\langle name \rangle$ not defined as a math alphabet

This error message is issued when you attempt to use $\backslash SetMathAlphabet$ on a $\langle name \rangle$ that was not previously declared with $\backslash DeclareMathAlphabet$ or $\backslash DeclareSymbolFontAlphabet$ to be a math alphabet identifier.

Command $\langle name \rangle$ not provided in base $\text{\LaTeX}2\epsilon$

You get this error for a handful of math symbols available in a “ \LaTeX symbol font” distributed with \LaTeX 2.09. These fonts are no longer loaded because that wastes one of the 16 precious math symbol font families (see page 739). If you need that symbol, load either `amsfonts` or the `wasysym` package.

Command $\langle name \rangle$ unavailable in encoding $\langle encoding \rangle$

Generated by $\backslash TextSymbolUnavailable$, which is these days very seldom used, because for most symbols suitable default mappings exist. If you get this error, it means that the symbol you attempt to typeset is not available in the current text encoding and you have to change the encoding.

Command $\langle name \rangle$ undefined

This error is triggered when you use $\backslash renewcommand$ with a $\langle name \rangle$ that is unknown to \LaTeX . Either $\langle name \rangle$ was misspelled or you should have used $\backslash newcommand$ instead.

It is also issued if you try to use $\backslash RenewDocumentCommand$ or $\backslash MakeRobust$ with an undefined command $\langle name \rangle$.

Corrupted NFSS tables

\LaTeX tried some font substitution and detected an inconsistency in its internal tables. This error happens if font substitution was triggered and the substitution rules contain a loop (i.e., some circular sub declarations exist) or when the default substitution arguments for the current encoding point to a nonexistent font shape group.

Counter too large

This error is produced if you try to display a counter value with `\fnsymbol`, `\alph`, or `\Alph` and the value is outside the available range for the chosen display form. See Section A.2.2 on page 650 for ways to work around this error.

Dimension too large TeX

TeX can deal only with absolute sizes that are less than 16383.99998pt (about 226 inches or 7.75 meters). Even on a huge page this range should be enough.

However, the error can also be triggered by packages such as `tikz` or `pgfplots` that internally use dimension registers for calculating coordinates. Even if the coordinates and plot values themselves are small, intermediate calculation steps involving, for example, divisions by small values can exceed TeX's limits.

`\displaybreak` cannot be applied here amsmath

An enclosing environment such as `split`, `aligned`, or `gathered` has created an unbreakable block.

Division by 0 graphics|graphicx

Usually, you get this error when you scale a graphic that has a height of zero. This can happen unintentionally—for example, if you specify `angle=-90`, `height=3cm` on `\includegraphics`. The rotation turns the image sideways, making the height zero, a value difficult to scale. In such a case use `totalheight` instead.

`\DocumentMetadata` should be only used before `\documentclass`

The `\DocumentMetadata` command provides data relevant to the whole document. Some of that information has to be specified at a very early stage, e.g., before the PDF (Portable Document Format) output file has been opened because it is already needed at this point. It must therefore be specified at first, and even though this is not strictly necessary for all document metadata, L^AT_EX prohibits its use after `\documentclass` has been seen, in order to ensure that all such data is stored in a single place.

Double subscript TeX

Two subscripts appear in a row (e.g., x_{i_2}), and L^AT_EX does not know whether you mean x_{i_2} or x_{i_2} . Add braces to indicate the subscripts: $x_{\{i_2\}}$.

Double superscript TeX

L^AT_EX found two superscripts in a row. See the explanation above.

Encoding file '`\<name>enc.def`' not found fontenc

If you ask for encoding `\<name>`, L^AT_EX tries to load the definitions for this encoding from the file `\<name>enc.def` (after converting `\<name>` to lowercase letters). If this file does not exist or cannot be found by L^AT_EX, you get this error message.

Encoding scheme `\<name>` unknown

The encoding `\<name>` you have specified in a declaration or in `\fontencoding` is not known to the system. Either you misspelled its name, you forgot to declare

it using `\DeclareFontEncoding`, or you need to load some font support package providing it.

End of environment '*<name>*' already defined (cmd)

When defining a new environment with `\NewDocumentEnvironment`, it checks that neither `\<name>` nor `\end<name>` is already defined. If only the latter is defined, you get this error message, otherwise the one below. In either case your definition is not made.

Environment *<name>* already defined

You try to declare an environment with `\newenvironment` with a *<name>* that already has a meaning in \LaTeX . Your declaration is ignored, and you have to choose a different name or use `\renewenvironment`. `\NewDocumentEnvironment` shows the same behavior.

Environment *<name>* undefined

You get this error if you use `\renewenvironment` on an environment name that is unknown to \LaTeX . Either the *<name>* was misspelled or you should have used `\newenvironment` instead. `\RenewDocumentEnvironment` shows the same behavior. This error is also triggered if you use `\begin` with a *<name>* that is not known to \LaTeX .

Erroneous nesting of equation structures; amsmath trying to recover with 'aligned'

Only certain `amsmath` display structures can be nested; `aligned` is one of these, so the system replaces a wrongly nested environment with it. This is probably not what you intended, so you should change the wrongly nested environment.

Extra & on this line amsmath

This error occurs only when you are using old `amsmath` environments that are not described in this book. If it does occur, then it is disastrous, and you need to check very carefully the environment where it occurred.

Extra alignment tab has been changed to `\cr` TeX

If you use an alignment structure, such as `tabular` or one of the display math environments (e.g., `eqnarray` or `split` from the `amsmath` package), then each row is divided into a defined number of columns separated by `&` signs. The error means that there are too many such characters, probably because you forgot a `\\` indicating the end of the row (`\cr` is \TeX 's name for the row end, but it is not a fully functional equivalent to `\\`).

Extra `\endgroup` TeX

\TeX has seen an `\endgroup` without a preceding matching `\begingroup`.

Extra `\middle` TeX

Your formula contains a `\middle` that is outside of a `\left...\right` construction. Recall that `\left/\right` pairs must be part of the same "subformula". They cannot, for example, be separated by `&` in an alignment or appear on different grouping levels.

Extra `\or` TeX

TeX encountered an `\or` primitive that has no matching low-level `\ifcase` conditional. The extra `\or` can be the result from a bad use of `\ifthenelse`.

Extra `\right` TeX

This error is issued by TeX if it finds a `\right` command without a matching `\left` in a formula. See advice on “Extra `\middle`” above.

Extra `}`, or forgotten `$` TeX

This error is triggered when math formula delimiters (e.g., `$...$`, `\[...\]`) and brace groups are not properly nested. TeX thinks it has found a superfluous `}`, as in `x}`, and is going to ignore it. While in this example the deletion of the closing brace is the right choice, it would be wrong in `\mbox{\(a)}`. There a closing `\)` is missing, so deleting the `}` produces additional errors.

Extra `}`, or forgotten `\endgroup` TeX

The current group was started with `\begingroup` (used, for example, by `\begin{...}`), but TeX found a closing `}` character instead of the corresponding `\endgroup`. You get this error if you leave a stray `}` inside a body of an environment.

File ‘*<name>*’ not found

LaTeX is trying to load the file *<name>* but cannot find it, either because it does not exist or because the underlying TeX program is looking in the wrong place. If the file exists but LaTeX claims it is not available, it is possible that your TeX installation uses a hashing mechanism to speed up file access, and you may have to run a special program to make your installation aware of newly installed files (e.g., `mktexlsr` with the TeX Live distribution).

The error is issued by commands like `\input` and `\usepackage` if they cannot find the requested file. You can suggest an alternate file in response to the error. If the new name is specified without an extension, the old extension is reused if known to LaTeX. If you want to omit loading the file, press *<Enter>*; to quit the run, type `x` or `X`. In some cases you might receive a similar low-level TeX error “! I can't find file ‘*<name>*’” that is slightly more difficult to quit; see the entry on page 725.

If a graphics file requested with `\includegraphics` is missing, it may help to press `h` to learn which extensions have been tried when looking for the file.

File ended while scanning *<something>* TeX

This error is part of a “Runaway . . .” error; check the explanations on page 736.

First argument of ‘*<declaration>*’ must be a command cmd

The first argument to `\NewDocumentCommand` or its siblings has to be the command that is going to be defined or redefined. LaTeX found something else instead, e.g., a character or several tokens.

Float(s) lost

One or more floats (e.g., `figure` or `table`) or `\marginpar` commands have not been typeset. The most likely reason is that you placed a float environment or

marginal note inside a box by mistake — inside another float or `\marginpar`, or inside a `minipage` environment, a `\parbox`, or a `\footnote`.

\LaTeX might detect this problem very late, such as when finishing the document. This can make it very difficult to find the offending place in the source. The best solution in this case is to halve your document repeatedly (for example, by using the primitive `\endinput`), until the fraction producing the error is small enough that you spot it.

If incorrect nesting is not the root cause, then you may have encountered a serious coding problem in the float algorithm, probably caused by some extra packages you loaded.

Font family `\enc)+\family` unknown

You tried to declare a font shape group with `\DeclareFontShape` without first declaring the font `\family` as being available in the encoding `\enc` using `\DeclareFontFamily`.

Font `\name` not found

\LaTeX 's internal font tables contain wrong information, so \LaTeX was unable to find the external font `\name`. Either this font was never installed, its `.tfm` file cannot be found by \TeX for some reason, or the `\DeclareFontShape` declaration referring to it contains a spelling error.

Font `\internal name)=\external name` not loadable: `\reason` \TeX

\TeX was unable to load a font with the \LaTeX name `\internal name` having the structure `\<encoding>/\<family>/\<series>/\<shape>/\<size>` in NFSS notation.¹ For example, it might say `\T1/cmr/m/it/10` (Computer Modern medium italic 10 points in T1 encoding). This should give you a good hint as to which font has a problem, even if you are not able to do much about it. There are two possible `\reason`s:

Bad metric (TFM) file \TeX

The \TeX metric file for the font (i.e., `\external name`.`tfm`) is corrupted. Your installation may have some utility programs to check `.tfm` files in detail, although this usually requires expert help.

Metric (TFM) file not found \TeX

The \TeX metric file for the font (i.e., `\external name`.`tfm`) was not found. Your installation may have a package (e.g., `cmbright`) to support a certain font family but the corresponding fonts are not available or are not properly installed.

Font `\internal name)=\external` not loaded: Not enough room left \TeX

\TeX can load only a certain number of fonts, and there was no space left to load `\internal name`. To find out which fonts are loaded, use the package `tracefmt` described in Section 9.5.8. One possible reason for excessive loading of fonts is the use of unusual font sizes for which \LaTeX has to calculate and load the corresponding math fonts; see Section 9.8.5 for details.

¹This is, in fact, a single command name, but due to the slashes in the name, you cannot enter it directly in your document, unless you use `\UseName{\<encoding>/\<family>/\<series>/\<shape>/\<size>}`.

Font $\langle font name \rangle$ not found

This error message is issued when there is something very wrong with a `\DeclareFontShape` declaration—perhaps it does not contain any size specifications. Check the setup for the font shape group in question.

Generic hooks cannot be added to ' $\langle command \rangle$ ' (hooks)

Generic hooks are added only to a $\langle command \rangle$ when code is added to the hook with `\AddToHook`. Such patching is sometimes impossible for a number of different reasons, and in that case you get this error. The precise reason is then given in the help text of the error message.

Hook ' $\langle name \rangle$ ' has already been declared (hooks)

If the same hook $\langle name \rangle$ is declared by different packages or classes, disaster is guaranteed, and this action is therefore disallowed. If you get this error, then the two packages are incompatible and cannot be used together.

Key ' $\langle key \rangle$ ' may only be used during loading of package ' $\langle name \rangle$ ' (keys)

The $\langle key \rangle$ /value option of package $\langle name \rangle$ is allowed only while the package is loaded, but not in a `\SetKeys` declaration.

Key ' $\langle key \rangle$ ' may only be used in the preamble (keys)

The $\langle key \rangle$ in question cannot be changed after `\begin{document}`, so you have to move it earlier into the preamble.

I can't find file ' $\langle name \rangle$ ' TeX

A low-level TeX error is raised when TeX cannot find a file that was requested to load. This error can be bypassed only by providing TeX with a file that it can find or by stopping the run altogether (if your operating system allows that). To get past this error, many installations offer a file `null.tex` so that you can reply `null` in response. \LaTeX normally uses the error message “File ' $\langle name \rangle$ ' not found”, which supports various user actions. However, depending on the package coding, you may get the current error instead.

I can't switch ' $\langle char \rangle$ ' on or off--not a shorthand. babel

When a user uses the command `\shorthandon` and passes it a $\langle char \rangle$ that is not defined to be a shorthand, this error message is displayed, and the instruction is ignored.

I can't write on file ' $\langle name \rangle$ ' TeX

TeX is not allowed to write data to the file $\langle name \rangle$. It is probably read-only, or you may not have writing permission for its directory. On some TeX implementations (e.g., those on the TeX Live CD), the error may be preceded by a line like the following:

```
tex: Not writing to /texmf/tex/latex/base/latex.ltx (openout_any = p).
```

These TeX installations are by default configured to be “paranoid” (hence, “p” above) when writing to files. They allow you to write only to files below the current directory and *not* to any files specified with an absolute path name or

starting with a dot in their name. To change that behavior you have to modify the settings in the file `texmf.cnf`.

Illegal use of `\AddToHook{<hook>}[top-level]{...}` (hooks)

The code label `top-level` is reserved for use in the preamble or document body to indicate last-minute hook code added by a user. The error is issued if a package or class adds code to a `<hook>` and attempts to label the code using this name.

Illegal character in array arg

You get this error if the column specification for a `tabular` or `array` environment or a `\multicolumn` command contains characters that are not defined as column specifiers to \TeX . A likely cause is that you used the extended syntax of the `array` package, described in Chapter 6, but forgot to load the package in the preamble (e.g., after you have copied a table from one document to another).

Illegal mode change in hook ‘`para/<name>`’. `<reason>` (hooks)

Paragraph hooks cannot contain code that changes the \TeX mode (unless it is done only temporarily within the hook). For example, `para/before` is not allowed to switch to horizontal mode, because that would trigger another call to the same hook code, ending in an endless recursion. If that happens, `<reason>` says what exactly is wrong. Examine the hook code with `\ShowHook` to find the issue.

Illegal parameter number in definition of `<command>` \TeX

This error occurs when a (re)defined command or environment uses `#<digit>` in the replacement text, with a digit higher than the declared number of parameters. This error can be implicitly caused by nesting declaration commands, such as `\newcommand`, and forgetting that inner commands refer to their arguments by doubling the `#` characters; see page 627 for details. Another possible cause is referring to environment arguments in the second mandatory argument of `\newenvironment` or `\renewenvironment`.

Illegal unit of measure (pt inserted) \TeX

You get this error if you misspell or forget the unit when specifying the value for a length parameter; see Section A.2.4.

Improper argument for math accent: \LaTeX

Extra braces must be added to prevent wrong output

The whole of the “accented subformula” must be surrounded by braces.

Improper discretionary list \TeX

This error is produced by \TeX if it encounters a `\discretionary` command whose arguments contain anything other than characters, boxes, or kerns, after expansion.

Improper `\hyphenation` \TeX

If you want to specify a hyphenation exception with `\hyphenation`, then you have to ensure that the argument contains only letters and `-` characters to

indicate the hyphenation points.¹ The problem is that, for example, accented characters in some font encodings are individual glyphs (allowed) but in other font encodings produce complicated constructs requiring the `\accent` primitive. For example, if the T1 encoding is used, then `ü` or `\"u` refers to a single glyph. Thus,

```
\usepackage[T1]{fontenc} \hyphenation{Tür-stop-per T\"ur-kin-ke}
```

are both valid. The same hyphenation exception used with the default OT1 encoding would produce this error. See page →1767 for an explanation of character differences in the major encodings.

Improper `\prevdepth` T_EX

You used `\the\prevdepth` or `\showthe\prevdepth` outside of vertical mode, which is not allowed. This error also shows up if you mistakenly placed a float (e.g., a figure or table) inside a math display environment.

Improper `\spacefactor` T_EX

You used `\the\spacefactor` or `\showthe\spacefactor` outside of horizontal mode, which is not allowed.

`\include` cannot be nested

ΛT_EX encountered an `\include` command inside a file loaded with `\include`. Because of implementation constraints, this is impossible. Either change the inner `\include` into `\input` or rearrange your document file structure so that all `\include` statements are in the main document file.

Incompatible list can't be unboxed T_EX

T_EX was asked to unpack a box with horizontal material while trying to build a vertical list, or vice versa. Either you encountered a serious programming error in a package or you used some commands in a way explicitly not supported. For example, the commands from the `soul` package produce this error when they are nested inside each other.

Incomplete `<conditional>`; all text was ignored after line `<number>` T_EX

A low-level T_EX conditional was unfinished (no matching `\fi`) when ΛT_EX reached the end of the current input file.

Infinite glue shrinkage found `<somewhere>` T_EX

To break paragraphs into lines or the galley into pages, T_EX assumes that there is no rubber length that can arbitrarily shrink, because that would mean that any amount of material can be placed into a single line or onto a single page. Thus, `\hspace{0pt minus 1fil}` in a paragraph or `\vspace{0pt minus 1fil}` between paragraphs is not allowed and raises this error (`<somewhere>` gives some indication about where the offending material was found).

Infinite shrinkage found in `'<region>'` (marks)

The current mark region, e.g., current column or page, contains some glue that can arbitrarily shrink. This makes it impossible to extract marks from that region.

¹ LuaT_EX offers an extended syntax for this.

This glue should not be present and indicates a coding error in a package or the \LaTeX kernel. Please report it to the appropriate maintainer.

Interruption \TeX

You get this “error” after interrupting the \LaTeX run (with Control-C or whatever your installation offers), so you should not be surprised by it. To finish the run prematurely, press x followed by $\langle\textit{Return}\rangle$. Just pressing $\langle\textit{Return}\rangle$ continues the run as if it was uninterrupted.

Invalid argument prefix ‘ $\langle\textit{prefix}\rangle$ ’ in $\langle\textit{command or environment}\rangle$ (cmd)

The definition for $\langle\textit{command or environment}\rangle$ used a $\langle\textit{prefix}\rangle$ in the argument specification that is not valid at the point it is used. As explained in the help text, this can have different reasons:

- There are two identical prefixes applied to a single argument specifier — one is redundant. Perhaps an argument specifier is missing?
- A ! prefix got applied to a mandatory argument or to an optional one followed by further mandatory ones. It is supported only for trailing optional arguments;
- A command defined with `\NewExpandableDocumentCommand` has a mixture of long (prefix +) and short arguments. The long ones must come last in expandable commands, but this is not the case;
- The > prefix is not supported with expandable commands.

Invalid argument type ‘ $\langle\textit{type}\rangle$ ’ in $\langle\textit{command or environment}\rangle$ (cmd)

A new command was defined with `\NewDocumentCommand` or one of its siblings, but its argument specification contains some $\langle\textit{type}\rangle$ that \LaTeX is not happy with. The help text gives further details; the most important reasons are:

- The specified $\langle\textit{type}\rangle$ does not correspond to any defined argument type — probably a misspelling;
- The $\langle\textit{type}\rangle$ is a deprecated type that is not made available by default — if you really need it, you have to load the `xparse` package in order to use it;
- The type `b` has been used with a command, but it is available only for environments;
- The specified $\langle\textit{type}\rangle$ cannot be used in expandable definitions, i.e., those made with `\NewExpandableDocumentCommand`. For example, `v` (verbatim) arguments are not available in that case.

Invalid argument $\{\langle\textit{arg}\rangle\}$ to `\IfBoolean...` (cmd)

The first argument to `\IfBooleanTF` or one of its variants has to be a special Boolean value, for example, the result of checking for a `*` in the arguments of a command defined with `\NewDocumentCommand`. \LaTeX found something else, hence the error message. Perhaps you passed it the wrong $\# \langle\textit{number}\rangle$ argument.

Invalid use of $\langle command \rangle$ amsmath

You have used an amsmath command in a place where it does not make sense. Look up the correct use of this command.

Keyboard character used is undefined in input encoding $\langle name \rangle$ inputenc

The 8-bit number encountered in the document is not mapped by the input encoding $\langle name \rangle$ to some LICR object (see Sections 9.5.4 and 9.9.3). Check whether the document is really stored in the specified encoding. These days it is usually best to store files in UTF-8 encoding and not load inputenc.

Invalid UTF-8 byte $\langle hex number \rangle$ or**Invalid UTF-8 byte sequence $\langle sequence \rangle$**

The document does not appear to be in UTF-8 encoding. In pdf \TeX , try adding `\UseRawInputEncoding` as the first line of the file or specify the correct encoding such as `\usepackage[latin1]{inputenc}` in the document preamble. Alternatively, save the file in UTF-8 using your editor or another tool.

Another possible cause is the use of multibyte UTF-8 characters with packages such as listings or soul that process their input on a character by character basis, but expect the characters to be single tokens (which is not the case for multibyte characters in pdf \TeX). In that case you have to either avoid or protect such characters in the input, switch to an alternative package, or use a Unicode engine. Search the Internet for advice about which option is best in your specific case.

Invalid UTF-8 byte or sequence ... replaced by U+FFFD Xe \TeX only

Unicode engines

The document processed by Xe \TeX does not appear to be in UTF-8 encoding. Offending bytes have been changed, but that is seldom the right corrective action. You have to make sure the input is encoded in UTF-8.

Labels ‘ $\langle label_1 \rangle$ ’ and ‘ $\langle label_2 \rangle$ ’ are incompatible in hook ‘ $\langle hook \rangle$ ’ (hooks)

The $\langle hook \rangle$ contains two code chunks labeled $\langle label_1 \rangle$ and $\langle label_2 \rangle$ that are incompatible with each other. This usually means that two packages were loaded that cannot be used together (with luck you can identify them from the label names). Depending on the severity of the issue, this message may show up only as a warning, not an error. In any case, the code for both labels is dropped.

Limit controls must follow a math operator \TeX

You can use `\limits` or `\nolimits` only following math operators such as `\sum`. See Table 11.6 for a list of common operator commands.

 $\backslash LoadClass$ in package file

The `\LoadClass` command is allowed only in class files; see Section A.6.

Lonely $\backslash item$ --perhaps a missing list environment

The `\item` command is allowed only within list structures, but \LaTeX believes that this one was found outside a list. In contrast to the “Something’s wrong—perhaps a missing `\item`” error, \LaTeX ’s diagnosis in this case is usually correct.

Mark class ‘ $\langle class \rangle$ ’ already defined (marks)

You try to declare a new mark class with `\NewMarkClass`, but the $\langle class \rangle$ name has already been used for that purpose. Your declaration is ignored, and you have to choose a different name.

Mark region ‘ $\langle region \rangle$ ’ not usable (marks)

The specified $\langle region \rangle$ in commands such as `\FirstMark` is not usable at this time; e.g., you cannot refer to `last-column` while \LaTeX is finishing the first column of a page.

Math alphabet identifier $\langle id \rangle$ is undefined in math version $\langle name \rangle$

The math alphabet identifier $\langle id \rangle$ was used in a math version ($\langle name \rangle$) for which it was not set up. An additional `\SetMathAlphabet` declaration should be added to the preamble of the document to assign a font shape group for this alphabet identifier.

Math version $\langle name \rangle$ is not defined

A math alphabet or a symbol font was assigned to a math version that is unknown to \LaTeX . Either you misspelled its name or you forgot to declare this version (perhaps you have to add some package file). It is also possible that the math version you selected with `\mathversion` is not known to the system.

Mismatched LaTeX support files detected. $\langle reason \rangle$

Since 2020, \LaTeX includes the L3 programming layer as part of the format. However, some parts of this layer are loaded later during document processing, and at that time \LaTeX might realize that the format and these additional support files do not match. This is a fatal error, and processing stops.

Most often the reason for this nasty surprise is the use of a local format that was previously built (by mistake?) and that did not get remade after the \TeX distribution was updated. To figure out which formats are available on the system, try running

```
kpsewhich -all -engine=pdftex pdflatex.fmt
```

if you are using \pdfTeX . For X_{\LaTeX} or \LuaTeX , the engine should be `xetex` or `luahtex` and the format `xelatex` or `lualatex`, respectively. If this returns more than one format file, remove the local one or make sure that it is properly regenerated. Further details on this can be found on the Internet.

Misplaced alignment tab character & \TeX

\LaTeX found an `&` character outside of `tabular`, `align`, or one of the other alignment environments. If you want to typeset `&`, use `\&` instead. A possible cause is use of the `amsmath` environment `cases` or `matrix` without loading the package.

Misplaced `\cr` or `\crcr` \TeX

A `\cr` is the \TeX low-level command for ending a row in an alignment structure (`\crcr` is a variation thereof); the corresponding \LaTeX command is `\\`. \TeX believes it came across such a command outside of an alignment structure.

Misplaced `\noalign` TeX

The TeX primitive `\noalign` is internally used to place “nonaligned” material between rows of alignment displays. It is therefore allowed only directly following the command that finishes a row. For example, you get this error when you use `\hline` outside of `array` or `tabular`, or not directly after `\\` within these environments.

Misplaced `\omit` TeX

The TeX primitive `\omit` is internally used to change the column specifications in an alignment display (e.g., to span rows with `\multicolumn` inside a `tabular`). The `\omit` command (and thus the commands calling it) is allowed only at the very beginning of an alignment cell (i.e., following `\\` or `&`).

Missing `\begin{document}`

This error occurs if typesetting is attempted while still within the document preamble.¹ It is most likely due to a declaration error that is misinterpreted by L^AT_EX. The error is also produced by text following `\begin{filecontents}` on the same line.

Missing control sequence inserted TeX

You used `\newcommand` or `\renewcommand` without providing a command name (starting with a backslash) as the first argument.

Missing `\cr` inserted TeX

TeX thinks it is about time to end the row in an alignment structure and inserted its low-level command for this purpose. In a L^AT_EX document, this guess is often wrong, so TeX's recovery attempt usually fails in such a case.

Missing delimiter (. inserted) TeX

A `\left`, `\middle`, `\right`, or one of the `\big..` commands was not followed by a delimiter. As corrective action, the empty delimiter “.” was inserted. See Section 11.5.6 on page 191 for details.

Missing `\endcsname` inserted TeX

This error can arise from using commands as part of the name of a counter or environment name (e.g., `\newenvironment{B1\ode}`).

These days it can also show up if you use anything other than characters or very simple commands to construct a file name for use with `\input` and similar commands. Trying to construct a file name using a fragile command, e.g.,

```
\input{test\ifthenelse{...}{a}{b}}
```

will fail and produce this strange error. Commands made explicitly robust (e.g., with `\MakeRobust`) are not executed but replaced by their name without a backslash, so that is most likely also not the desired result.

¹Typesetting inside an `\sbox` or `\savebox` declaration within the preamble is allowed, but it is usually wise to move such declarations after `\begin{document}`, because some packages may delay their final setup until that point.

Missing number, treated as zero TeX

This error occurs when TeX is looking for a number or a dimension but finds something else. For example, using `\value{page}` instead of `\thepage` would produce this error, because an isolated `\value` makes TeX expect a low-level counter assignment. In general, using a length register without a proper mutator function like `\setlength` can trigger this error. You also get this message when `\usebox` is not followed by a box bin defined with `\newsavebox`, because internally such bins are represented by numbers.

One other surprising scenario is due to a limitation in TeX's implementation of integer and length expressions involving parentheses: you cannot start an expression with `+(` or `-(`. In that case add a 0 to change the `+` or `-` from an unary to a binary symbol; see Example A-2-12 on page 659.

Missing p-arg in array arg

There is a `p` column specifier not followed by an expression in braces (containing the width) in the argument to `tabular`, `array`, or `\multicolumn`.

Missing @-exp in array arg

There is an `@` column specifier not followed by an expression in braces (containing the inter-column material) in the argument to `tabular`, `array`, or `\multicolumn`.

Missing # inserted in alignment preamble TeX

An alignment preamble specifies the layout of the columns in an alignment structure. Internally, TeX uses `#` to denote the part of the column that should receive input. In L^ATeX this is unlikely to appear as a first error.

Missing = inserted for \ifnum TeX

TeX complains that the low-level `\ifnum` conditional is not followed by two numbers separated by `<`, `=`, or `>`. This error can occur when you forget the comparison operator in `\ifthenelse`.

Missing = inserted for \ifdim TeX

The low-level `\ifdim` conditional is not followed by a comparison between two lengths.

Missing \$ inserted TeX

TeX has encountered something in normal text that is allowed only in math mode (e.g., `\sum`, `\alpha`, `\wedge`), or something that is not allowed inside math (e.g., `\par`) while processing a formula. It has therefore inserted a `$` to switch to math mode or to leave it. If, for example, you tried to get an underscore by simply using `_` instead of `_`, L^ATeX would typeset the rest of the paragraph as a formula, most likely producing more errors along the way.

Missing \endgroup inserted TeX

This error indicates that a grouping structure in the document is incorrectly nested. Environments internally use `\begingroup` and `\endgroup`, and for some reason TeX thinks that such a group was not properly closed. If you cannot

determine why the group structure is faulty, try using the `\showgroups` or `\tracinggroups` commands, as explained on page 747.

Missing `\right.` inserted TeX

Your formula contains a `\left` without a matching `\right`. Recall that `\left/\right` delimiter pairs must be part of the same “subformula”; they cannot, for example, be separated by `&` in an alignment or appear on different grouping levels.

Missing `{` inserted TeX

TeX thinks there is an open brace missing and inserted one. This error is, for example, caused by a stray `}` inside a `tabular` cell.

Missing `}` inserted TeX

Something is wrong in the grouping structure of the document, and TeX tries to recover by inserting a closing brace. This attempt either gets it onto the right track again or causes you to receive more errors. Usually, the problem becomes apparent if you look at the typeset output. If you cannot determine why the group structure is faulty, try using the `\showgroups` or `\tracinggroups` commands, as explained on page 747.

Multiple `\label`’s: `label <label> will be lost` amsmath

Within the `amsmath` display environments, you can have only one `\label` per equation. It is usually best to remove or replace all but the last, because it is the only one that is effective.

Multiple `\tag` amsmath

Within the `amsmath` display environments, you can have only one `\tag` command per equation. All but the first are ignored.

No counter ‘<name>’ defined

The counter `<name>` referenced in either `\setcounter`, `\addtocounter`, or the optional argument of `\newcounter` or `\newtheorem` is unknown to L^AT_EX. It must first be declared with `\newcounter`.

No declaration for shape **

The `sub` or `ssub` size function used in a `\DeclareFontShape` command refers to a substitution shape that is unknown to L^AT_EX’s font selection scheme.

No driver specified color|graphics|graphicx

The package `graphics`, `graphicx`, `color`, or `xcolor` was loaded without specifying a target device option. On most installations this is done using the configuration files `graphics.cfg` and `color.cfg`.

No room for a new *<register>* TeX

The packages loaded in your document require more internal registers (`\count`, `\dimen`, ...) than there are available in TeX. These days this error should not happen because L^AT_EX is using all registers available in the engine, which is a

huge number. So if you are getting this, then there is probably a coding issue in a package so that it allocates registers over and over again. To debug that you may need external help.

The only exception are `\write` registers: most engines have only 16 registers available, and if you run out, then you can load Bruno Le Floch's `morewrites` package to get additional (virtual) registers at the cost of processing speed.

No `\title` given

A \LaTeX class has executed `\maketitle` without seeing a `\title` declaration. Only `\date` is optional when this command is used.

Not a letter \TeX

You specified a hyphenation exception with `\hyphenation`, but the argument to this command contained some characters that \TeX does not consider to be letters. For example, `\hyphenation{la-ryn-gol-o-gist's}` would produce such an error because `'` is not a “letter” in \TeX 's categorization.

Not in outer par mode

This error is issued when a `\marginpar` or a float environment, such as `table` or `figure`, is encountered inside a box-producing command or environment. For instance, you cannot use a `\marginpar` in a footnote, a float, a `tabular`, or a similar place (because all of them produce boxes). Move the offending object to the main galley.

Not in vertical mode

Starting a paragraph with `\RawIndent` or `\RawNoindent` is allowed only if \LaTeX is in vertical mode. Because these commands are intended for programmers and not for ordinary use in documents, getting this error most likely means that there is a bug in some package.

Number too big \TeX

You assigned or used a number in `\setcounter` or `\addtocounter` that is larger than the largest number that \TeX can handle (2147483647, hexadecimal 7FFFFFFF). This error can also happen when modifying a length register with `\setlength` or `\addtolength`.

OK \TeX

You used the \TeX tracing command `\showbox` or `\showlists` and the parameter `\tracingonline` is positive. After displaying the data, \LaTeX stopped with this message to allow for some interaction on the command line (e.g., entering `i\show..` to view some other values). If `\tracingonline` is zero, no data is shown on the terminal and the message is slightly different; see below.

OK (see the transcript file) \TeX

You used the \TeX tracing command `\showbox` or `\showlists`, without also directing \LaTeX to display the result on the terminal. The data is written only to the transcript (`.log`) file. Use also `\showoutput` to display it on the terminal.

Old form `<command>` should be `\begin{<envname>}` amsmath

You have used `cases`, `matrix`, or `pmatrix` in its non-`amsmath` command form (probably with its old internal syntax). Change to the `amsmath` environment form with standard internal syntax.

Only one # is allowed per tab TeX

This error indicates a broken alignment template. In \LaTeX it should not occur, unless caused by a fragile command in a moving argument.

Option clash for package `<name>`

The package `<name>` was requested twice with a conflicting set of options. When you press H in response to this error, \LaTeX shows you the sets of conflicting options. Because \LaTeX loads a package only once,¹ the best solution is to specify all options on the first occasion.

If this is not possible, because the package is already loaded as part of the class or another package, you can try to specify the required options as global options to the `\documentclass` command. In an emergency you can even load a package before `\documentclass` by using `\RequirePackage`. See Section 2.1.2 on page [–I 24](#) for details.

Alternatively, adding a suitable `\PassOptionsToPackage` declaration before the package gets loaded might work; this is described in Section A.6.4 on page 697.

Page height already too large

You used `\enlargethispage` on a page whose vertical size is already larger than 8191.99998pt, or roughly 113 inches. \LaTeX thinks that this is dangerously large and does not extend the page size as requested.

Paragraph ended before `<command>` was complete TeX

As discussed in Section A.1.2, commands defined with `\newcommand*` or `\renewcommand*` and by default all arguments of `\NewDocumentCommand` and friends (unless their arguments are specified with a `+`) are not allowed to contain `\par` or an empty line. If they do, you get a Runaway argument together with this error. The `<command>` listed may not be the one used in your document. For example, `\emph{.. \par ..}` lists `\text@command` in the error message (i.e., the internal command called by `\emph`).

pdfTeX error (font expansion): auto expansion is only possible with scalable fonts pdfTeX/LuaTeX

This engine message is issued if you use the `microtype` package together with non-scalable fonts, e.g., those produced by METAFONT, and `microtype` tried to use font expansion. Set `expansion` to `false` in regions where such fonts are used for typesetting or switch to a different font family that is scalable.

(Please type a command or say ‘\end’) TeX

You have replied with `<Return>` in response to `*`. See the first entry on page 717.

¹The only exception is the `fontenc` package, which can be loaded as often as needed with different options; see Section 9.5.5 on page [–I 693](#).

`\pushtabs` and `\poptabs` don't match

You issued a `\poptabs` command in a tabbing environment, but there was no previous `\pushtabs` command issued.

Requested version '*<version>*' for '*<package or class>*' is unknown

In the second optional argument of `\usepackage` or `\documentclass` you can request a specific version of the package or class using either a date or a named *<version>* label. The version specified, e.g., `=V2`, is not known to \LaTeX .

Required argument missing for *<command or environment>* (cmd)

A command defined with `\NewDocumentCommand` or one of its siblings has an argument specification that includes a delimited mandatory argument (specified with `r` or `R`). In the document body this command is used without providing this argument, and as a result you see this error message.

`\RequirePackage` or `\LoadClass` in Options Section

A `\RequirePackage` or `\LoadClass` was found inside a package or class file between the `\DeclareOption` commands and `\ProcessOptions`. Loading packages or classes in this part is not allowed because it would clobber the data structure holding the current set of options; see Section A.6 for details. If you want to load a package when a certain option is specified, use a flag to indicate that the option was selected and load it after the `\ProcessOptions` command has done its job.

Rotation not supported `graphics|graphicx`

You have requested rotation with `\rotatebox` or a similar command, but the selected graphics driver does not support the rotation of objects. \LaTeX leaves the right amount of space, but the printed document might show the image in the wrong position.

Runaway *<something>* `\TeX`

\TeX thinks it has scanned too far while looking for the end of *<something>*, where *<something>* can be either *argument*, *definition*, *preamble*, or *text*. Unless low-level \TeX code is at fault, the most likely cause is *argument*. For example, if you forgot the closing brace of an argument, it might cause \TeX to scan until it reaches the end of the file or until its memory is filled — whichever comes first. Incomplete definitions done with `\newcommand`, `\newenvironment`, and so forth also claim that the *argument* has run away. Only low-level definitions, involving \TeX primitives like `\def`, produce a Runaway definition.

A Runaway preamble means that an alignment structure has problems (that should not occur in normal \LaTeX documents), and Runaway text usually refers to a token register assignment (this should never happen unless there is a serious package implementation error).

In contrast to the situation with normal error messages, you do not get a line number that indicates where the error was detected (because \TeX often has reached the end of the file). Instead, you see the beginning of the material

that was being absorbed. For example, if you have a definition without the final closing brace,

```
\newcommand\foo{bar
\begin{document} Some text \end{document}
```

you get

```
Runaway argument?
{bar \begin {document} Some text \end {document}
! File ended while scanning use of \@argdef.
<inserted text>
\par
<*> samplefile.tex
?
```

The fact that T_EX in that case inserted `\par` as a recovery action is of little help, because the complete document was already swallowed. Instead of “File ended while...”, you might see some other message at this point, such as “Paragraph ended before...”.

Scaling not supported graphicsgraphics

You have requested scaling with `\resizebox` or a similar command, but the selected graphics driver does not support scaling of objects. L^AT_EX leaves the right amount of space, but the printed document will show the image at the original (unscaled) size.

Something’s wrong-perhaps a missing `\item`

This error message is produced by an `\addvspace` command when encountered in horizontal mode. The follow-up remark about “perhaps a missing `\item`” is unfortunately seldom correct. For example, forgetting the closing brace on `\mbox` as in `\mbox{... \section{...}}`... would produce this error, because the `\section` command that executes `\addvspace` internally is now used in horizontal mode.

Identify which command issued the `\addvspace` causing the error, and check whether that command was used incorrectly. Refer to page 655 for an in-depth discussion of the `\addvspace` command.

Sorry, I can’t find *<format>* ... T_EX

If you get this message, then L^AT_EX never started because T_EX did not find the *<format>* containing the basic L^AT_EX definitions. There is a problem with your T_EX installation, and you have to consult the installation documentation.

Sorting rule for ‘*<hook>*’ hook applied too late ... (hooks)

`\DeclareHookRule` was used to declare a sorting rule for the one-time hook *<hook>* after the hook was executed. Since such hooks are executed only once, the rule came too late, and you get this error message.

Suggested extra height (*<value>*) dangerously large

Using the *<value>* with `\enlargethispage` would make the resulting page too large (more than 113 inches or 2.87 meters) for L^AT_EX's liking.

Suspicious rollback date given

If you use the `latexrelease` package, you can roll back your L^AT_EX release (and a number of supporting packages) to an earlier point in time to process your document as if it were processed with a version current then. If this results in this error message, then the offended package has no rollback information for the date and claims it was not in existence back then.

This may just be spurious due to incomplete data but may also indicate an issue with the package. In any case L^AT_EX continues using the earliest version it knows about.

Symbol font *<name>* is not defined

You tried to make use of the symbol font *<name>*—for example, within a `\DeclareMathSymbol` command—without declaring it first with a suitable `\DeclareSymbolFont` declaration.

Tab overflow

L^AT_EX supports up to 13 tabulator positions (`\=`) inside a `tabbing` environment, and you have used a larger number. If not all of them are needed at the same time, you can try solving the problem by using `\pushtabs` and/or providing template lines with `\kill`.

`\tag` not allowed here amsmath

The `\tag` command is allowed only within the top level of a mathematical display. It is usually best to move it to the end of the logical equation in which it occurs.

TeX capacity exceeded, *<explanation>* TeX

T_EX ran out of some sort of memory and died. This error is discussed in detail in Section B.2 on page 744.

Text line contains an invalid character TeX

The input file contains a strange, nonprinting character that is rejected by T_EX. This may happen if you used a word processor to create the file and did not save it as “text”.

The attribute *<attrib>* is unknown for language *<lang>* babel

You tried to activate an attribute for a language *<lang>* that is not defined in the language definition file for this language. Check the documentation of `babel` with respect to this language.

The font size command `\normalsize` is not defined...

A class file needs to provide a minimal setup, including a definition for `\normalsize`; see Section A.6.11 on page 710 for details.

There's no line here to end

This error is triggered if `\newline` or `\\` is found outside a paragraph (i.e., after a `\par` or an empty line). If the intention was to produce extra vertical space, use `\vspace` or any of the other commands described on page 654.

This file needs format ‘*<format name>*’

The current input file is not processed further, because it was written for a different flavor of \TeX .

This may be a LaTeX bug

This is an error message dating back to 1986, and to the author’s knowledge, until now this message never actually signaled a \LaTeX bug. It means, however, that \LaTeX got thoroughly confused by previous errors and lost track of the state of its float data structure. It is best to stop and correct previous errors first.

This should not happen. *<reason>*

In contrast to the previous message, this message was introduced recently, and the developers are fairly confident that it signals an error in the coding of \LaTeX . After giving a *<reason>*, it continues and tells you where to report the bug.

This NFSS system isn’t set up properly

This error occurs when \LaTeX detects a mistake while trying to verify the font substitution tables at `\begin{document}`. It means that either a `\DeclareFontSubstitution` or `\DeclareErrorFont`¹ declaration is corrupted. These declarations need to point to valid font shapes (declared with `\DeclareFontShape`). Type `h` for additional information and inform your system maintainer. If you are the system maintainer, read the end of Section 9.8.3.

Too deeply nested

Standard \LaTeX supports a total of six levels of lists nested in each other. Those levels can include up to four lists of type `itemize` or `enumerate`. This error signals that your document has overflowed one of these limits. You probably have forgotten to end some list environments properly.

If you really need additional levels and you use the `enumitem` package, you can increase the overall default using `\setlistdepth`. However, the restrictions on the number of nested `itemize` or `enumerate` environments is fixed, and if you require further levels there, you need to copy the base definitions into a private package and modify their hardwired constants.

Too many arguments for ‘*<command or environment>*’ (cmd)

\LaTeX supports command or environment definitions with a maximum of nine arguments, but your `\NewDocumentCommand` or `\NewDocumentEnvironment` declaration asks for more.

Too many columns in eqnarray environment

The `eqnarray` environment supports a maximum of three columns (i.e., two `&` signs per row). For serious math, consider the `amsmath` package described in Chapter 11, which allows for more complex display structures.

Too many math alphabets used in version *<name>*

You used too many different math alphabet identifiers or symbol fonts in your

¹The declaration `\DeclareErrorFont` is used during installation and points to a font (font shape + size) that should be used when everything else fails. Its default is Computer Modern Roman 10pt, which should be available with any \TeX installation. See [113] for further details.

formulas. If this error occurs after adding the `bm` package to the preamble, define `\newcommand\bmmax{0}` before loading `bm` and try again; this prevents the package from preallocating math alphabets. There is also the possibility to increase the counter `localmathalphabets` to keep a higher number of alphabets flexible; see the discussion on page →1681 for details.

Too many symbol fonts declared

This error is generated by `\DeclareSymbolFont` if it cannot install another symbol font because all available math families are already in use either by symbol fonts or by math alphabet identifiers (see previous error). It usually happens if you load too many math font packages that try to compete for the precious few math font families — a total of 16. Other than the advice on `bm` given above, all you can easily do is to load fewer font packages. The only other (more complicated) possibility is to define special math versions that selectively load only some of the symbol fonts and switch between them as needed. See Section 9.8.5, and especially the discussion about math versions on page →1753, for the necessary declarations.

Too many ‘*<token(s)>*’ separators in argument (cmd)

\TeX was asked to split the argument of a command or environment a number of times as a given set sequence of *<token(s)>* using `\SplitArgument`, but these tokens were found more often than expected. For example, with `\SplitArgument{1}{,}` you would divide an argument into two parts at a comma. If you then pass it `{2,3,5}`, you would get this error.

Too many unprocessed floats

Floats that cannot be placed immediately are deferred by \TeX , possibly causing subsequent floats to be deferred as well. By default \TeX can defer up to 18 floats before you receive this error message. This limit can be increased by using `\extrafloats{number}` in the preamble, but if there is a float that cannot be placed for some reason, this change merely delays receiving the above error. See Chapter 7 for ways to deal with this situation.

This error can also be triggered if you have too many `\marginpar` commands within a single paragraph. A `\marginpar` temporarily uses two storage bins for deferred floats as long as the current paragraph has not been typeset (this allows a maximum of nine marginal notes per paragraph, or fewer if there are already some deferred floats).

Trying to overwrite ‘*<name>.tex*’

The `filecontents` environment allows overwriting existing files under certain circumstances, but it always refuses to overwrite the file `\jobname.tex`, assuming that this is the file it is currently processing, because that would mean disaster. You can still shoot yourself in the foot by giving your file a different extension and then asking to overwrite it.

Two `\documentclass` or `\documentstyle` commands

Only one such command is allowed per document. Your document includes more than one, perhaps as the result of combining two originally separate documents.

Two `\LoadClass` commands

A class can load at most one other class to do the bulk of processing. See Section A.6 for a detailed discussion of how classes are built.

Undefined color `<name>` color

You have requested a color with `\color` or a similar command from the `color` or `xcolor` package without previously defining it with `\definecolor`. See [55] or the `color` package documentation for details.

Undefined control sequence TeX

This is perhaps the most common of all \TeX errors, though it shows up as a \TeX error message: you have used a command name that was not previously defined. Often you may have simply mistyped the name in your document (e.g., `\bmox` instead of `\mbox`).

To carry on in such a case, you can respond with `i\mbox`, inserting the correct name. You can then continue processing and correct your source document afterwards. It is also possible to get this error as a result of using a fragile command in a moving argument.

Undefined font size function `<name>`

A size function used in `\DeclareFontShape` was misspelled. Check the entry or tell your system maintainer.

Undefined tab position

This error is raised if you try to advance in a tabbing environment with `\>`, `\+`, `\-`, or `\<` to a tabulator position that was not previously set up with `\=`. Either the `\=` is actually missing or perhaps you used `\+` or `\pushtabs` and got confused when specifying the tabular position to which you actually want to move.

Unknown filecontents option `<option>`

The `filecontents` environment allows a combination of `overwrite` (alias `force`), `noheader`, and `nosearch` in its optional argument. The option `<option>` is not among them; maybe it was misspelled?

Unknown float option ‘`<letter>`’

All float environments support an optional argument to specify the allowed positions. This can contain a combination of the letters `!htbp` in any order (and if the float or another extension package is loaded, also `H`). The specified `<letter>` is not among them and will be replaced by `p`.

Unknown graphics extension: `<ext>` graphics/graphics

You get this error if you try to load a fully specified graphics file (with extension `<ext>`) and the graphics driver does not know the particular extension and there is no default rule set up. The `dvips` program, for example, interprets every unknown extension as EPS, so with this driver you never see this error but probably others.

Unknown mark class ‘*<class>*’ (marks)

You try to insert a mark with `\InsertMark`, but the specified *<class>* is not known to the mark mechanism. Either you misspelled the *<class>* name or you forgot to make a `\NewMarkClass` declaration for it.

Unknown option ‘*<language>*’. *<reason>* [babel]

When \LaTeX processes the option list for `babel` and encounters an unknown option *<language>*, it tries to load a file by the name of *<language>.ldf*. This message is displayed when \LaTeX fails to find it. This error can be caused by a simple typing mistake, or the file might not be stored on \LaTeX ’s search path.

Unknown option ‘*<option>*’ for package ‘*<name>*’ (keys)

You specified an *<option>* for package *<name>* that is not declared by that package. Packages that accept key/value pairs as options produce a similar error, but prefix it with `LaTeX keys Error`. Consult the package documentation on the available options.

Unknown relationship ‘*<rel>*’ between labels ‘*<label₁>*’ and ‘*<label₂>*’ in hook ‘*<hook>*’ (hooks)

`\DeclareHookRule` was used to declare a relationship between two hook labels, but *<rel>* is neither `<`, `>`, `before`, `after`, `incompatible-warning`, `incompatible-error`, `voids`, nor `unrelated`. Perhaps a misspelling?

Use of ‘*\???*’ does not match its definition

This is a low-level \TeX error, artificially generated by \LaTeX to give some information about the *real* error that happened at an awkward moment. The important information comes two lines later and should be a text that can be looked up in this appendix. See page 714 for further explanation.

Use of ‘*<command>*’ does not match its definition [\TeX]

Low-level macro definitions made with `\def`, instead of `\newcommand` and friends, sometimes require special argument delimiters (e.g., the *<coord>*) of the picture commands). If *<command>* is a \LaTeX command, check its syntax.

Otherwise, this is most likely a spurious error due to using a fragile command in a moving argument without `\protect`. If *<command>* is `\???`, see the previous entry.

`\usepackage` before `\documentclass`

The `\usepackage` declaration can be used only after the main class was loaded with `\documentclass`. Inside a class or package file you have to use `\RequirePackage` instead.¹

Unicode character ‘*<char>*’ (`U+<hex number>`) not set up for use with \LaTeX

The Unicode character denoted by the UTF-8 notation `U+<hex number>` is not known to \LaTeX . How the *<char>* is displayed depends on the engine setup: it may appear as a single glyph, e.g., “ Δ ”, or as `^^e2^^88^^86`, which is of little help.

¹It is technically possible to load a package before a class by using `\RequirePackage`, but this should be avoided unless you know what you are doing.

Under the precondition that the character is available in a font encoding used in the document, it has to be set up using the `\DeclareUnicodeCharacter` declaration; see Section 9.9.3 on page 1758.

`\verb ended by end of line`

To better detect errors, the argument of `\verb` must be placed on a single line. Thus, this error signals that either you forgot the final delimiter for the argument or the argument was broken over several lines in the source. In the case of very long arguments, it may help to split them over several `\verb` commands and, if necessary, mask a line break between them in the source with a % sign.

`\verb illegal in argument`

Except in very special situations (explicitly documented in this book), it is not possible to use `\verb` (or `verbatim`) in the argument of other commands or environments. If you need verbatim text in such a place, use, for example, `\verbdef` from the `newverbs` package or `\SaveVerb` and `\UseVerb` from the `fancyvrb` package; both are described in Section 4.2.

Verbatim-like *<command or environment>* ended by end of line (cmd)

Commands defined with `\NewDocumentCommand` can have “verbatim” arguments similar to those of `\verb`. For them the same precaution (discussed above) is implemented; i.e., they have to appear on a single line in the source file. The same is true for environments declared with `\NewDocumentEnvironment`.

Verbatim-like *<command or environment>* illegal in argument (cmd)

With `\NewDocumentCommand` or `\NewDocumentEnvironment` you can define commands and environments that have “verbatim” arguments. Just like `\verb` they cannot appear in arguments of other commands or environments except in very special circumstances (see discussion above). If they cause problems, you get this error message and usually several more afterwards. See Section 4.2 for ways to deal with this issue.

Wrong syntax for `\DeclareFontSeriesDefault`

With `\DeclareFontSeriesDefault` one can set the series default for the `md` (medium) or `bf` (bold) series, so those are the two values allowed in the first mandatory argument. The optional argument specifies the “meta” font family. Currently supported values there are `rm` (Roman), `sf` (Sans Serif), or `tt` (Typewriter). Any other value generates this error message.

You already have nine parameters TeX

TeX supports command or environment definitions with a maximum of nine arguments (called parameters by TeX), but your `\newcommand` or `\newenvironment` specified 10 or more.

You can't use ‘macro parameter #’ in *<some>* mode TeX

TeX found a stray # character somewhere that does not seem to be a reference to an argument of some command. If you wanted to typeset this symbol, use `\#` instead.

You can't use '`\spacefactor`' in vertical mode TeX

TeX lets you refer to the `\spacefactor` only when you are building a horizontal list. You get this error when you use the \LaTeX command `\@` outside of a paragraph. Because many internal commands start with an `@` in their names, you might also get this error if you use code containing such internal commands (e.g., `\@startsection`) without surrounding it with `\makeatletter` and `\makeatother`. In that case TeX sees `\@` followed by the letters `startsection`, and a later use of this code then executes `\@` that in turn produces this error message.

You can't use '`\prevdepth`' in horizontal mode TeX

The `\prevdepth` dimension can be used only while in vertical mode (i.e., between paragraphs).

You can't use '`\end`' in internal vertical mode TeX

This is one of the more misleading TeX error messages, because it refers to the TeX primitive `\end` (ending a TeX run) that was redefined by \LaTeX to become the end-tag of environments. The error means that \LaTeX 's `\end{document}` or the `\stop` command was encountered while \LaTeX was building a box. For example, `\begin{figure}...\stop` would generate it.

You can't use '`\command`' in *<some>* mode TeX

TeX complains that *<command>* is not allowed in one of its modes. Some specific variations of this theme have already been discussed. If you have not used *<command>* directly, then the most likely cause for this error is a broken fragile command in a moving argument.

You haven't defined the language *<lang>* yet babel

Various user interface commands of `babel` check whether their argument contains a language that was specified in the option list when `babel` was loaded or there is at least an `.ini` file for it. If the *<lang>*uage was *not* specified and no `.ini` file can be found, processing is stopped, and this error message is displayed.

B.2 Dying with memory exceeded

The TeX program contains a number of internal tables of fixed size used for storing away different kinds of information needed at run time. Whenever any of these tables overflows, \LaTeX aborts with a “TeX capacity exceeded” error.

Until the mid-1990s, memory problems could, in fact, be due to the size of the document. In some cases it was impossible to process a document as a whole.¹ These days such limitations are gone or are at least less severe. For one, the average TeX implementation is already equipped with huge internal tables. In addition, most implementations allow you to modify the table sizes via configuration files instead

¹The first edition of this book required a specially compiled version of the TeX program with all such tables enlarged by a factor of 10 and could be processed only on a large Unix workstation.

of requiring you to manually recompile T_EX. In some cases you may have to generate a new L^AT_EX format; for more details, consult the documentation of your T_EX distribution.¹

Nevertheless, people experience this dreadful error once in a while, usually as the result of a faulty command definition. Below are four candidates reduced to the bare bones of the problem we want to discuss — in reality, such problems usually lurk in more complex definitions:

```
\newcommand\FAILa{.\FAILa}          \newcommand\FAILb{\FAILb x}
\newcommand\FAILc{\typeout{.}\FAILc} \newcommand\FAILd{.\par\FAILd}
```

If you execute `\FAILa` as defined above, you receive the following output (the reported memory size possibly differs) after a short while:

```
! TeX capacity exceeded, sorry [main memory size=5000000].
\FAILa ->.
      \FAILa
```

The main memory is the part of T_EX in which macro definitions and the material for the current page are stored. Looking at the above recursive definition, it is clear that it generates a never-ending sequence of periods. Because paragraph breaking is deferred until T_EX sees a `\par` command or a blank line to globally optimize the line breaks, T_EX waits in vain for a chance to break the paragraph material into lines.

Exceeding main memory because of too many macro definitions is less likely these days. Nevertheless, even that can happen (in theory) if the size of this memory is small and you load many packages, have a large number of huge deferred floats, or use macro packages that produce new macros on the fly.²

If you get this error only with larger documents and L^AT_EX actually produces pages before giving up, you can try to find out whether the memory is gradually filling up (which suggests a table size problem) by setting `\tracingstats=2` in the preamble of your document. T_EX then reports the main memory status after finishing each page, producing output like the following:

```
[765]
Memory usage before: 4262&161788; after: 1286&157691; still untouched: 1323176
[766]
Memory usage before: 3825&160983; after: 636&156520; still untouched: 1323176
[767]
Memory usage before: 3652&160222; after: 771&156307; still untouched: 1323176
```

The number reported to the left of the `&` is the memory devoted to large objects such as boxes; the number on the right is the amount of memory used by macro definitions

¹The T_EX Live distribution, for example, lets you specify the size of most tables through the configuration file `texmf.cnf`. See the T_EX Live manual for details.

²For example, `varioref` defines two labels internally for every use of `\vref`, which can result in a noticeable amount of memory consumption in large documents.

and character data. Thus, one can expect a reduction in both values whenever a page has finished (i.e., the `after:` value). If the right-hand value is slowly increasing, however, then something is probably adding more and more definitions.

If we use `\FAILb`, we overflow a different table. Here the recursion happens before \LaTeX actually reaches the end on the macro expansion and thus needs to store away the unprocessed part of the expansion.

```
! TeX capacity exceeded, sorry [input stack size=10000].
\FAILb ->\FAILb
x
```

With today's size for the `input stack`, this message usually appears only if a recursion like the one above makes that stack grow at a frightening speed. In a normal \LaTeX document you seldom find nested definitions that make this stack grow beyond a value of 50 (even for this book the maximum value was only 107).

What happens if you execute either `\FAILc` or `\FAILd`? Both are similar to `\FAILa`, but neither overflows any internal \TeX table. Instead, both simply fill your hard disk. The only action of `\FAILc` is to show periods on your screen and in the transcript file, thereby very slowly filling up the disk with a huge transcript. `\FAILd`, on the other hand, contains a `\par` in its definition and therefore is able to typeset paragraphs (each consisting of a single dot); as a result it produces pages in rapid succession. Such an experiment ended on the author's machine with a document containing 22279 pages and the following message:

```
tex: fwrite: No space left on device
```

On your private machine, this is merely a nuisance, easily rectified. On systems with shared resources, however, you should be careful when letting \LaTeX run unattended. This type of error once hit a student very badly; this individual processed such a document on a mainframe in batch mode without a time or size limit and was presented a bill for computer processing time of several thousand dollars.

Several other internal tables can overflow in principle. Below is the complete list of those not already discussed, along with an explanation for the most likely reason for the overflow. Some additional information can be found in [84, p.300].

buffer size The characters in the lines being read from a file. Because the default size is usually quite large, the most likely cause for an overflow is lost line breaks due to a faulty conversion of a file during transfer from one operating system to another. A buffer overflow can also be caused by some PC word processing programs, which internally put an entire paragraph on a single line even though the text appears to be broken into several lines on the screen.

exception dictionary The number of hyphenation exceptions as specified by `\hyphenation`. \LaTeX has some exceptions specified for the English language, and some language packages specify additional exceptions. However, if this table overflows, you must have been doing a very thorough job.

font memory The font metric data loaded by \LaTeX . These days an overflow is unlikely but not impossible. If it happens, \LaTeX has loaded too many fonts — probably

because you used many different font sizes and \LaTeX calculated and loaded math fonts for all the sizes. Increase the table size, if possible, or refer to Chapter 9 for information on how to reduce the number of fonts.¹

grouping levels The number of unfinished groups that delimit the scope for setting parameters, definitions, and other items — for instance, braces, the start of environments, or math mode delimiters. An overflow usually indicates a programming error (e.g., a definition that opens more groups than it closes). That type of error is sometimes difficult to identify. Good help is available with the command `\showgroups` to produce a listing of stacked groups starting with the innermost one. For example, placing it into the footnote on the current page yields

```
### semi simple group (level 3) entered at line 2955 (\begingroup)
### insert group (level 2) entered at line 2955 (\insert0{)
### semi simple group (level 1) entered at line 2921 (\begingroup)
### bottom level
```

The semi simple group on level 1 is due to the fact that this text is typeset in a description environment (the `\begin` command issues internally a `\begingroup` command). The `\footnote` command is implemented with the \TeX primitive `\insert`, which contributes level 2. In fact, another semi simple group is started by `\footnote`, which ensures that color changes remain local. What we can deduce from this example is that the relationships among top-level document commands and internal groups are far from obvious or simple. However, the line numbers that show when a group was entered do help, because there are usually no long-ranging groups in normal documents.

As an alternative, use the internal tracing counter `\tracinggroups`. If it is set to a positive number, the entry and exit of groups is recorded in the transcript file; with `\tracingonline` having a positive value, this information also appears on screen.

hash size The number of command names known to \TeX . Most packages contribute a fixed number of new command names. Each `\label` or `\bibitem` command in the document generates one new internal command name. Thus, packages that internally use the `\label` command (e.g., `varioref`) may significantly contribute to filling that table in large documents.

number of strings The number of strings — command names, file names, and built-in error messages — remembered by \TeX . In some cases \TeX is able to free unused space, but usually such strings survive even if they are used only locally. One possible reason for overflowing this table is the use of many files in an application. Each opening for reading or writing of a file contributes, even when the same file is used many times over.

¹It happened during the production of this book, but only when typesetting both volumes together — this loaded more than 4000 fonts, and we had to increase the table size slightly.

For historical reasons, \TeX has a somewhat unusual string-handling concept involving several tables, each of which can overflow. Thus, if you change the hash size to allow for more commands, you may need to adjust the number of strings and quite likely the pool size, and vice versa.

parameter stack size The total number of command parameters of nested commands being expanded but not yet fully processed. For example, suppose a command with 4 arguments calls a command with 5 arguments, which in turn calls a command with 3 arguments, thereby using up 12 slots in this table. The moment \TeX reaches the end of a macro replacement text it frees the stack. Thus, with today's implementations it is quite difficult to hit that limit, unless you use a flaky recursive definition with arguments, for example:

```
\newcommand\FAIL[3]{\typeout{Got #1, #2, and #3 but \FAIL is a mess}\DO}
```

Do you see the problem? Because the `\typeout` contains `\FAIL` by mistake, it gets called again, before its replacement text has been fully processed (picking up the characters `i`, `s`, and `a` as arguments). As a result, `\DO` is never executed and we finally get

```
! TeX capacity exceeded, sorry [parameter stack size=10000].
\FAIL #1#2#3->
\typeout {Got #1, #2, and #3 but \FAIL is a mess}\DO
1.18 \FAIL 123
```

This is similar to the `\FAILb` example from page 746, except that because of the number of arguments the **parameter stack** overflowed first.

pattern memory The memory available to store hyphenation patterns. This table cannot overflow during normal document processing, because such patterns are loaded only during format generation. If you receive this error during that process, reduce the number of languages for which you load hyphenation patterns into your format. Pattern loading is normally defined in the file `language.dat`.

pool size The characters in strings — command names and file names (including the full path on some implementations). If this table overflows, the most likely cause is the use of too many files, especially if they have long absolute path names. This can, for example, happen if a document includes many graphics and one uses `\graphicspath` to make \LaTeX search for the images in several directories — every attempt to open a file contributes to this string pool.

save size The set of values to restore when a group ends. With today's default limits, this is again difficult to overflow. The most likely cause is the use of both local and global assignments to the same object, something that can happen only through the use of low-level \TeX programming, because \LaTeX assignments are either always local (for most types) or always global (e.g., counter assignments). But, of course, many packages are built using low-level methods, which means such bugs in a package are not impossible.

To avoid unnecessary growth of the `save stack`, the document environment has a special implementation so that it does not produce a group (as normal environments do). Without it every new definition would automatically push an unnecessary “undefined” value onto the `save stack` — unnecessary, because by the time that group would end, all processing would stop anyway.¹

semantic nest size The number of token lists being worked on simultaneously.

Boxes, math formulas, and other elements start a new list, suspending work on the current structure. Once they are finished, \TeX has to continue constructing the suspended object, so all such unfinished objects are remembered in the `semantic nest stack`. With a default size of several hundred objects, it is very difficult to get even close to this limit with normal documents.² In an emergency, \TeX offers `\showlists`, which displays all unfinished lists that \TeX is currently working on.

text input levels The number of simultaneously open input sources (e.g., files opened with `\include`, `\input`, or `\usepackage`, etc.). On the author’s implementation of \TeX one would need to nest 1500 files to reach this limit.

B.3 Warnings and informational messages

While error messages make \LaTeX stop³ and wait for user input, warning messages are simply displayed on the terminal and in the transcript file, and processing continues. If applicable, \LaTeX also shows the source line number that triggered the warning. The warnings are prefixed by “`LaTeX Warning:`” or “`LaTeX <module> Warning:`” if they are issued by the core \LaTeX code. Otherwise, they identify the issuing package or class by starting with “`Package <name> Warning:`” or “`Class <name> Warning:`”, respectively. \TeX warnings, such as “`Overfull . . .`”, have no standard prefix string.

In addition to warnings, \LaTeX writes informational messages to the transcript file — usually without displaying this information on the terminal. To better distinguish between informational and warning messages, **warnings are shown in blue** and informational message in black in the following alphabetical listing.

Calculating math sizes for size *<text size>*

\LaTeX has to guess the correct font sizes for subscripts and superscripts because it could not find the information for the current *<text size>* in its internal tables. This message usually is followed by several font size correction warnings because \LaTeX ’s initial guess is seldom successful. This situation can arise when you select an uncommon size using the `\fontsize` command; see Section 9.8.5 if the math formulas look strange.

¹As a side effect it is impossible to use `\begin{document}` inside another environment because the grouping structure is not obeyed.

²The author could not think of any problematic definition that would not hit any of the other limits first.

³This is of course true only if you have not issued a `\scrollmode` or `\nonstopmode` command. In that case all the errors discussed earlier will also be just flush by, or, if `\batchmode` is used, nothing at all is shown. The only exceptions are “File not found” errors: for them \LaTeX stops in `\scrollmode` and asks for help, or gives up in despair in the other two modes.

Cannot activate hook ‘*<hook>*’ because it is disabled! (hooks)

This warning is issued by `\ActivateGenericHook` if the *<hook>* has been explicitly disabled via `\DisableGenericHook`, because it is not functional for one or the other reason.

Cannot remove chunk ‘*<label>*’ from hook ‘*<hook>*’ because *<reason>*! (hooks)

This warning is issued by `\RemoveFromHook` if the code to be removed does not exist (i.e., there is no code with that *<label>*) or if the *<hook>* does not exist.

Checking defaults for *<enc>/*

This message is written in the transcript file at `\begin{document}` while \LaTeX is verifying that the substitution defaults for the encoding *<enc>* are sensible. It is followed either by `...okay` or by an error message that is generated when the ** group specified with `\DeclareFontEncoding` is unknown to \LaTeX .

Citation ‘*<key>*’ on page *<number>* undefined

The *<key>* specified as an argument to `\cite` or `\nocite` is not defined by a `\bibitem` command or you need another run of \LaTeX (and perhaps \BibTeX or `biber`) to make it known to \LaTeX . The latter case is indicated by an additional warning, “Label(s) may have changed...”, as discussed on page 754. The page number is omitted if the warning is emitted by `\nocite`.

Command *<name>* invalid in math mode

This is either a warning or an error message indicating that you have used a command in math mode that should be used only in normal text. A warning is generated when an obsolete, yet still valid, construction is used.

Command *<name>* has changed

A test was made in some package to see if *<name>* has its expected meaning (usually in order to change it afterwards). This is no longer the case so that there is some likelihood that the modification is no longer adequate — hence the warning. Sometimes it does not matter, but usually it is best to contact the package developers so that they can update the package.

Defining command *<name>* with sig. ‘*<argument spec>*’ (cmd)

Defining environment *<name>* with sig. ‘*<argument spec>*’

This information is written to the transcript file if a new document-level command *<name>* was declared with the help of `\NewDocumentCommand`. For reference its signature, i.e., its argument specification, is also given. The same kind of information is recorded for environments declared with `\NewDocumentEnvironment`.

Document Class: *<name>* *<date>* *<additional info>*

This line is produced by a `\ProvidesClass` command in the document class code. Although not a warning, it appears both on the terminal and in the transcript file. If a document produces different output on different installations, you should compare the “Document Class:”, “File:”, and “Package:” messages to identify any release differences.

Empty ‘thebibliography’ environment

This warning is issued if a thebibliography environment has no `\bibitem` commands. It often indicates a problem with a BibTeX run. For example, the BibTeX program may have been unable to resolve a single citation.

Encoding *<name>* has changed to *<new name>* for *<symbol font>* ...

This message is issued when in the declaration of a symbol font different encoding schemes in different math versions have been used. It may mean that the `\DeclareMathSymbol` commands for this symbol font are not valid in all math versions.

(\end occurred *<when>*) TeX

You receive this warning at the very end of your run whenever TeX finds the `\end{document}` or `\stop` command to be premature. As a warning the message is unfortunately misleading, because it refers to a TeX primitive `\end` that was reused by L^ATeX to become the environment end-tag. The *<when>* can be one of two cases:

inside a group at level *<number>*) TeX

In this case the L^ATeX run ended while there were still some open groups. Such groups include explicit braces that are not closed (e.g., `{\itshape...}`), use of `\bgroup` and `\begingroup` in macro code without their counterparts, and unclosed environments in the source. The latter normally triggers a suitable L^ATeX error first (i.e., “`\begin{env}`” on...) unless you ended the run with `\stop`, because in that case no check for mismatched environments is made.

when *<condition>* on line *<line number>* was incomplete) TeX

In this case L^ATeX completed the run while a low-level TeX conditional remained unfinished. With L^ATeX documents using only standard commands, this problem should not occur unless you ended the document inside a file loaded with `\include`. In other cases it probably means there is a bug in a package. Try to identify the source of the conditional (by looking at the *<line number>*) to see in which command it was used. Note that the *<line number>* may not be in the current file — unfortunately, TeX does not divulge the file name. In very difficult situations you can try to use eTeX’s advanced tracing options to pinpoint the problem: if `\tracingifs` is set to 1, you get detailed trace information about nested conditionals as they are executed.

External font *<name>* loaded for size *<size>*

L^ATeX has ignored a request to load some font shape at size *<size>* and has loaded the external font *<name>* instead. This message is generated by the size functions `fixed` (as a warning) or by the size function `sfixed` (as an informational message).

Faking *<command>* for font family *<name>* in TS1 encoding

The glyph *<command>* is not available in the TS1 encoding of the current font family. L^ATeX has responded by “faking” it in some way. This is, for example, done for the `\texteuro` glyph (€), if unavailable in the current font.

File ‘*<name>*’ already exists on the system.
 Not generating it from this source

This informational message is generated by a `filecontents` environment when the file *<name>* already exists somewhere in the search path of \LaTeX , even if it would not be overwritten. If you want to unpack the file nevertheless, either delete (or rename) the version found by \LaTeX or use the option `overwrite` in the optional argument of the environment.

File: *<name>* *<date>* *<additional info>*

This line is produced from the `\ProvidesFile` command used to identify a file and its last modification date. By convention, the *<additional info>* starts with a version number, though it is not required. Although of the same importance as `\ProvidesClass`, this information is written only to the transcript file to avoid cluttering the terminal with messages.

If a document produces different output on different installations, you should compare the “Document Class:”, “File:”, and “Package:” messages to identify any release differences. A good way to do this is by adding `\listfiles` in the preamble of your document. This then summarizes such information for all relevant files at the end of the document.

File: *<encoding>**<family>*.*fd* *<date>* *<additional info>*

This important special case of the previous informational message indicates that a font definition file for some *<encoding>* (usually displayed in lowercase) and *<family>* combination was loaded. Such files contain font shape group declarations and are described in Section 9.8.4.

First page is already shipped out, ignoring *<command>* (hooks)

This warning is generated by `\AtBeginDvi` or `\AtBeginShipoutFirst` if the declaration is used too late, i.e., after the first page has already been shipped out.

Float too large for page by *<value>*

A float is too tall by *<value>* to fit in the current `\textheight`. It is printed on a page by itself (if permitted), thereby possibly overflowing into the bottom margin. If the float is not allowed to go on a float page, it prevents all further floats in its class from being placed.

Font shape ** has incorrect series value ‘*<value>*’

The NFSS convention for font series names in *.fd* files is to drop the *m* if there is a second value, e.g., *c* not *mc* for medium-condensed. Obeying this convention is important, because otherwise automatic adjustments are not fully functional.

If you see this message, it usually originates from an *.fd* with incorrect data and needs to be reported to the font maintainer. It is not a warning message, because as a user you have no easy way to correct the problem other than reporting it.

Font shape ** in size *<size>* not available

\LaTeX issues this message when it tries to select a font for which the requested font attribute combination is not available and a substitution is defined in the

internal tables. Depending on the contents of these tables, one of the following additional messages is issued:

external font $\langle name \rangle$ used

\LaTeX has selected the external font $\langle name \rangle$ in that particular situation and does not know to which font shape group it belongs. (This message is generated by the size function subf.)

size $\langle size \rangle$ substituted

\LaTeX has selected the correct shape, but because the requested size is not available, \LaTeX has chosen the nearby size $\langle size \rangle$. This action is taken automatically if none of the simple sizes or size ranges in the $\langle font\ shape \rangle$ group declaration matches.

shape $\langle font\ shape \rangle$ tried

\LaTeX has selected a different $\langle font\ shape \rangle$ group because the requested one is not available for the requested $\langle size \rangle$. (This message is generated by the size function sub.)

Font shape $\langle font\ shape \rangle$ will be scaled to size $\langle size \rangle$

\LaTeX has loaded the requested font by scaling it to the desired size. To print a document containing scaled fonts, your printer driver must have these fonts in the correct size or must be able to scale them automatically.

Font shape $\langle font\ shape \rangle$ undefined. Using ‘ $\langle other\ shape \rangle$ ’ instead

This warning is given when a combination of font attributes is specified for which \LaTeX has no font shape definition.

For example, requesting `\fontseries{b}\ttfamily` would normally trigger this warning, because Computer Modern fonts have neither bold typewriter nor bold extended typewriter. However, when the latter combination is requested, you do not receive this warning but only some information in the transcript file because for `\textbf{\texttt{...}}` the .fd files contain an explicit substitution rule.

If \LaTeX identifies a particular symbol that it cannot typeset in the requested shape, the above warning is followed by “for symbol $\langle name \rangle$ ”.

Foreign command $\langle command \rangle$;

amsmath

$\frac{}{} or \genfrac should be used instead$

Although the use of $\langle command \rangle$ is not an error, you are strongly discouraged from using this old form for your (generalized) fractions in \LaTeX . Use the `amsmath` commands instead.

Form feed has been converted to Blank Line

The `filecontents` environment detected a “form feed” character (\char"000D) in the source and writes it as an empty line (`\par` command if interpreted by \LaTeX) into the external file. Because `filecontents` was designed to distribute textual data, it cannot be used for handling arbitrary binary files.

Freeze math alphabet allocation in version $\langle version \rangle$

The number of allocated math alphabets (with `\DeclareMathAlphabet`) and math symbol fonts (with `\DeclareSymbolFont`) in a given math $\langle version \rangle$ has reached the threshold defined by the counter `localmathalphabets`. The remaining math groups are assigned only locally (per formula) in order to allow different formulas to use the remaining slots in different ways. See page →1681 for details.

`'h' float specifier changed to 'ht'` or
`'!h' float specifier changed to '!ht'`

You specified `h` or `!h` as a float placement without giving any other options. \LaTeX requires some alternative in case “here” leads to an impossible placement because not enough room is left on the current page. If you really want to prevent floats from floating, consider using the `float` package described in Section 7.3.1.

Hook `'shipout/lastpage'` executed on wrong page ... (hooks)

\LaTeX made a wrong guess and executed the `shipout/last` hook on a page that was not the last one. Rerun your document and the problem goes away.

Hyphen rules for `'\langle lang_1 \rangle'` set to `\l@{\langle lang_2 \rangle} (\language\langle number \rangle)` babel

Many languages explicitly request some hyphenation replacements in the corresponding `.ldf` files. Because not all patterns are available on all systems, these messages help when debugging problems. For additional information, use the package option `showlanguages` to get a list of all hyphenation patterns available in the format and the $\langle number \rangle$ s that they are associated with.

Ignoring text `'\langle text \rangle'` after `\end{\langle env \rangle}`

This warning is issued by `filecontents` or `filecontents*` when textual material is detected following the `\end` tag.

Ignoring void shipout box

There was a request to produce a page (via `\shipout`), but the `\ShipoutBox` contained no material. There may be something wrong with the code producing the page or one of the output routine hooks; e.g., `shipout/before` voided the box. If done deliberately, then it is better to use `\DiscardShipoutBox` that avoids this warning.

Label `'\langle key \rangle'` multiply defined

The document contains two or more `\label` commands with the same $\langle key \rangle$. References to this $\langle key \rangle$ always refer to the last `\label` defined. Ensure that all $\langle key \rangle$ s are different.

Label(s) may have changed. Rerun to get cross-references right

\LaTeX has detected that the label definitions, as compared to those in the previous run, have been modified and that (at least) one additional \LaTeX run is necessary to resolve cross-references properly. In theory it is possible, though unlikely, that this message persists regardless of the number of processing runs.¹ If this

¹For example, if the `\label` is near the page boundary between pages “iii” and “iv”, the use of

is the case, compare the `.aux` files of different runs to determine which label alternates between different states and resolve the problem manually.

Last declared language option is ‘`\lang`’, but the `\babel`
last processed one was ‘`\other lang`’

The main document language is set to the last declared in either the class or the package options. However, when languages are declared in *both* places, the behavior is not well defined, and this warning alerts you to this fact. The recommended setup is to request them only as class or as package options, but if for some reason you need both, you can set the main language with the package option `main=\lang`.

Loose `\hbox` (badness `\number`) `\somewhere` `\TeX`

`\TeX` produced a horizontal box with a badness of 13 or greater (which corresponds to using 50% or more of the available stretchability). This warning can be safely ignored unless you are a perfectionist; in fact, it will not be produced unless you change the default for `\hbadness`. See the message “Underfull `\hbox`...” on page 762 for more details.

Loose `\vbox` (badness `\number`) `\somewhere` `\TeX`

`\TeX` produced a vertical box with a badness of 13 or greater (which corresponds to using 50% or more of the available stretchability). The warning is produced only if `\vbadness` was set to a value below 100. See the message “Underfull `\vbox`...” on page 763 for more details.

Making `\char` an active character `\babel`

For each character that is turned into a shorthand character, this informational message will be written to the transcript file. When a document shows unexpected results, this information might help if the problems are caused by inadvertent use of a shorthand character.

Marginpar on page `\number` moved

A `\marginpar` could not be aligned with the text line to which it was originally attached, because a preceding `\marginpar` already occupies the space.

Missing character: There is no `\char` (`\hex number`) in font `\name` `\TeX`

Although this message usually indicates a serious problem, it is unfortunately shown only if `\tracinglostchars` is positive. It means that somewhere in the source a request for a symbol `\char` was made for which the current font (`\name` is the external name) has no glyph in the corresponding position. The displayed `\char` may differ on different `\TeX` installations.¹ The `\hex number` is shown only on some installations. For example, using the command `\symbol`

 Watch out for this message in the transcript or turn it into an error!

`\pageref` before the `\label` might result in a situation where the `\label` is moved to page “iv” if the textual reference “iii” is used, and vice versa.

¹Sometimes you see something like `^G` and sometimes real characters are displayed. Unfortunately, there is no guarantee that they correspond to your input: some translation that depends on the operating system may happen when the characters are written to the transcript file.

can produce this warning because you can ask for any font slot with this command. However, standard font-encoding-specific commands, as discussed in Section 9.9.4 on page 767, should never produce this warning.

In 2021 the engines got extended, and you can now set `\tracinglostchars` to different values: 1 (transcript only), 2 (terminal warning), or 3 (TeX error). For compatibility reasons, L^AT_EX sets it to 2, but because of its importance, especially with Unicode engines, we recommend using `\tracinglostchars=3` in the preamble of your documents.

No `\author` given

You used `\maketitle` without specifying an author first. In contrast to a missing `\title` this omission generates a warning.

No auxiliary output files

This information is displayed when you use a `\nofiles` declaration in the document preamble.

No characters defined by input encoding change to `<name>`

The input encoding file `<name>.def` does not seem to contain any input encoding declarations. For the `ascii` encoding, this is the expected behavior; for all other encodings, it indicates a problem.

No file `<name>`

L^AT_EX displays this information whenever it tries to read from an auxiliary file (e.g., `.aux` or `.toc`) but cannot find the file. This is not considered an error because such files are created only after the first run. However, the same routine is also used by `\include`, so that, unfortunately, a missing “include file” triggers this unsuspicious warning too.

No hyphenation patterns were preloaded for the language babel `'<lang>'` into the format

All language definition files check whether hyphenation patterns for the language selected were loaded into the L^AT_EX format (provided the line breaking is based on this mechanism). If this is not the case, this message is displayed, and a default set of hyphenation patterns is used instead. The default patterns are those loaded into pattern register 0 (typically American English).

No positions in optional float specifier. Default added ...

A float environment (e.g., `figure` or `table`) was used with its optional placement argument, but it did not contain any suitable information. Hence, L^AT_EX used its default placement rules.

Oldstyle digits unavailable for family `<name>`

You used `\oldstylenums` with a font family that does not contain oldstyle digits. As an emergency measure, L^AT_EX used oldstyle from a different font instead. By default this is an informational message; if you prefer a warning or error

on the terminal, load the `textcomp` package with the option `warn` or `error`. Section 9.5.6 gives further details.

Optional and mandatory argument with same delimiter ‘*char*’ (cmd)

If you define a command with mandatory and optional arguments following each other and using the same argument delimiters, e.g.,

```
\NewDocumentCommand \mycmd { d<> * r<> }{...}
```

then it is impossible to use such a command and omit all the optional arguments, simply because \LaTeX would interpret `<X>` in `\mycmd<X>` as the optional argument and then complain about a missing required one. You could, however, call it without problems as `\mycmd*<Y>`, `\mycmd<X><Y>`, or `\mycmd<X>*<Y>`. Thus, the uncommon declaration might be intentional, and therefore \LaTeX gives only a warning, not an error.

Optional argument of `\twocolumn` too tall on page *<number>*

The material in the optional argument to `\twocolumn` was so tall that fewer than three lines remain on the page. \LaTeX does not start two-column mode on the current page and starts a new page instead.

`\oval`, `\circle`, or `\line` size unavailable

The requested size for the mentioned commands is unavailable. \LaTeX chooses the closest available size. See, for example, Section 8.3.2 for ways to avoid this problem.

Overfull `\hbox` (*<number>*pt too wide) *<somewhere>* \TeX

\TeX was forced to build a horizontal box (e.g., the line of a paragraph or a `\makebox`) of a certain width and was unable to squeeze the material into the given width, even after shrinking any available space as much as possible. As a result, the material sticks out to the right. In most cases this is quite noticeable, even if the total amount is small. You have to correct this problem manually, because \TeX was unable to resolve it (Sections 3.1 on page 1121 and B.4.3 give some advice). For a list and explanation of the possible origins (i.e., the *<somewhere>*), see the warning “Underfull `\hbox`...” on page 762.

Overfull `\vbox` (*<number>*pt too wide) *<somewhere>* \TeX

\TeX was asked to build a vertical box of a fixed size (e.g., a `\parbox` or a `minipage` with a second optional argument; see Appendix A.3.2 on page 666) and found more material than it could squeeze in. The excess material sticks out at the bottom. Whether this result poses a problem depends on the circumstances. For a list and explanation of the possible origins (i.e., the *<somewhere>*), see the warning “Underfull `\vbox`...” on page 763.

Overwriting encoding scheme *<something>* defaults

This information is written by `\DeclareFontEncodingDefaults` to the `.log` when it overwrites previously declared system-wide defaults for “text” or “math”.

Overwriting *<something>* in version *<name>* ...

A declaration, such as `\SetSymbolFont` or `\DeclareMathAlphabet`, changed the assignment of font shapes to *<something>* (a symbol font or a math alphabet) in math version *<name>*.

Package: *<name>* *<date>* *<additional info>*

This line is produced by the `\ProvidesPackage` command, which is used to identify a package and its last modification date. By convention, the *<additional info>* starts with a version number, though it is not required. Although of the same importance as `\ProvidesClass`, this information is written to just the transcript file to avoid cluttering the terminal with messages. If a document produces different output on different installations, you should compare the “Document Class:”, “File:”, and “Package:” messages to identify any release differences.

Package ‘*<name>*’ has already been loaded: ignoring (keys)
load-time option ‘*<option>*’

Some packages have options that can be applied only during package loading, but not altered with `\SetKeys` afterwards. If such an *<option>* is found, it is ignored with a warning. You get this warning when there are several attempts to load a package (of which only the first is carried out). In that case the warning may be harmless or it may indicate a serious problem — \LaTeX just does not know, and you have to check yourself.

pdfTeX warning (dest): name{*<name>*} has been referenced pdfTeX only
but does not exist, replaced by a fixed one

This is a pdfTeX engine warning that indicates that the document contains an internal hyperlink to a destination that does not exist. This happens, for example, when you use `\includeonly` and you have links from your document into files not included. As a replacement, pdfTeX creates a link pointing to the first page.

Unicode engines

There is a similar warning when the LuaTeX engine is used, starting “warning (pdf backend)”. It too creates an artificial destination, but one to the current page. With \XeTeX , however, no warning is given, because resolving links happens in a separate program. With that program, the link is simply dead when selected.

pdfTeX warning (ext4): destination with the same identifier pdfTeX only
(name{*<name>*}) has been already used, duplicate ignored

This happens if two destinations are created with the same name. A typical case is sections numbered without a chapter number. `hyperref` then creates the destination `section.1` in the first chapter and again in the following chapters. The remedy is to redefine `\theHsection` so that it gives an unique number, e.g.:

```
\renewcommand\theHsection{\thechapter.\thesection}
```

You also get the warning if the page numbering is reset with `\pagenumbering` without changing the number style, for example, after a title page. In that case `hyperref` creates the destination `page.1` twice. The remedy here is either to use a different number style, e.g., `alph`, for the title page, even if the number is not visible, or to surround the title page with the `NoHyper` environment so that no destinations are created at all.

Redeclaring font encoding *<name>*

This information is recorded if `\DeclareFontEncoding` is used for an encoding that is already defined (thereby potentially changing its defaults).

Redeclaring math accent *<name>*

This information is recorded if `\DeclareMathAccent` is used for a math accent that was previously declared. If the command to be declared is known but not an accent, you get an error message instead.

Redeclaring math alphabet *<name>*

A `\DeclareMathAlphabet` or `\DeclareSymbolFontAlphabet` command was issued to declare *<name>*, which was already defined to be a math alphabet identifier. The new declaration overrides all previous settings for *<name>*.

Redeclaring math delimiter *<name>*

The command *<name>* was already declared as a math delimiter, and its renewed declaration with `\DeclareMathDelimiter` overrides the old definition. If the *<name>* is known but not a delimiter, you get an error instead.

Redeclaring math symbol *<name>*

Same as above but for math symbols redeclared with `\DeclareMathSymbol`.

Redeclaring math version *<name>*

A package or class (or you) issued a `\DeclareMathVersion` command for a version that was already declared. The new declaration overrides all previous settings for this version with the default values.

Redeclaring symbol font *<name>*

A package or class issued a `\DeclareSymbolFont` command for a symbol font that was previously declared. The new declaration overrides the symbol font in all known math versions.

Redefining command *<name>* with sig. '*<argument spec>*' (cmd)

Redefining environment *<name>* with sig. '*<argument spec>*'

An already existing command or environment *<name>* was redefined using `\RenewDocumentCommand` or `\RenewDocumentEnvironment`, respectively. The new (and possibly changed) argument specification is also recorded.

Reference '*<key>*' on page *<number>* undefined

A reference created with `\ref`, `\pageref`, or one of the other cross-reference commands discussed in Chapter 2 used a *<key>* for which \LaTeX has not seen a

corresponding `\label` command. If the `\label` is somewhere in the document, you simply need another \LaTeX run to make it known to \LaTeX . This situation is indicated by the additional warning “Label(s) may have changed...” discussed on page 754.

Size substitutions with differences up to `<size>` have occurred

This message appears at the end of the run if \LaTeX selected at least one significantly different font size because a requested size was not available. The `<size>` is the maximum deviation that was needed.

Some font shapes were not available, defaults substituted

This message appears at the end of the run if \LaTeX had to use automatic font substitution for some font shapes.

Suspicious rollback/min-date date given

There was a rollback request through the `latexrelease` package and at the same time an explicit request with a conflicting date in the second optional argument to `\usepackage` or `\documentclass`. Maybe this was intentional, but equally likely, it is the result of a leftover configuration that was not updated.

Symbol `<command>` not provided by font family `<name>`

The TS1 font encoding is unfortunately implemented fully by just a minority of the font families usable with \LaTeX . If a symbol requested from this encoding is not available in the current font, it is instead typeset using a default family, and you get this informational message. You can turn such messages into warnings or errors by loading the `textcomp` package with the option `warn` or `error`. See Section 9.5.6 for more details.

Tab has been converted to Blank Space

The `filecontents` environment detected a “tab” character (`^~I`) in the source and writes it as a space into the external file. Because `filecontents` was designed to distribute textual data, it cannot generally handle arbitrary binary files.

Temporary extra page added at the end

For a number of tasks \LaTeX has to write configuration data to the very end of the last page. It makes an initial guess when it is about the ship out this last page, but this guess is sometimes wrong. In such cases \LaTeX is forced to produce an extra page just to ship out the necessary information. If that happens, it issues this warning and advises you to rerun the document. Just like with cross-references it then makes use of the knowledge from the previous run to correct the issue. The same can happen if you make extensive changes (mainly deletions) so that the information from the previous run is no longer accurate.

Text page `<number>` contains only floats

One or more floats processed as “top” or “bottom” floats are together so tall that very little space (less than two lines) is left for normal text on the current page. Therefore, \LaTeX decided to place only floats on the page in question (even if some or all of the floats do not explicitly allow for this placement). This message can

appear only when the placement parameters for floats were changed drastically from their default values; see the beginning of Chapter 7 for details.

The following font families will use the default `\babel` settings for all or some languages: `\details`

Unicode engines

With Unicode engines, Babel automatically selects some OpenType features for the text fonts so that they are properly rendered in many languages and scripts. These default font settings may not always work. This informational message therefore shows what got selected so that you can make adjustments using `\babelfont` if that is necessary. If everything comes out fine, you can ignore this warning.

There were multiply-defined labels

This warning appears at the end of a \LaTeX run when \LaTeX detected at least one pair of `\label` or `\bibitem` commands with the same key. Check the transcript file and make sure that all keys used are different.

There were undefined references

This warning appears at the end of a \LaTeX run when \LaTeX detected unresolved references. If \LaTeX also displays “Label(s) may have changed. Rerun ...” then follow its advice and rerun the document.

However, if the message appears on its own, then \LaTeX has concluded that rerunning the document would not resolve the references. In that case you should check the transcript file for all occurrences of “Reference `\langle key \rangle` undefined” and “Citation `\langle key \rangle` undefined” and correct them, either by fixing a misprint or by adding the necessary `\label` or `\bibitem` commands. In the case of missing citation `\langle keys \rangle`, all you may have to do is regenerate the bibliography with `BibTeX` or `biber` and then rerun \LaTeX .

Tight `\hbox` (badness `\langle number \rangle`) `\langle somewhere \rangle` \TeX

\TeX produced a horizontal box and had to shrink the interior spaces. You get this message only if `\hbadness` is set to a value less than 100. See the message “Underfull `\hbox`...” on the next page for more details.

Tight `\vbox` (badness `\langle number \rangle`) `\langle somewhere \rangle` \TeX

\TeX produced a vertical box and had to shrink the interior spaces. You get this message only if `\vbadness` is set to a value less than 100. See the message “Underfull `\vbox`...” on page 763 for more details.

Token not allowed in a PDF string (`\langle encoding \rangle`): removing ‘`\langle token \rangle`’ `\hyperref`

When converting input such as a section title into the format suitable for bookmarks, `hyperref` has to produce a simple character string and therefore removes or replaces commands as necessary. Depending on what it has to change, it may issue this warning. Commands that it does not know how to handle are removed, but their arguments will remain and may become part of the string.

In the special case of spacing commands like `\`, or `\quad`, `hyperref` warns about a `\kern` or a `\hspace` and either removes it (if it is small) or replaces it by a single space. If the text contains a formula, `hyperref` issues at least two warnings about removing a “math shift” at the beginning and the end. Superscripts and subscripts in the math will be removed with a warning. In all cases the bookmarks should be checked, and, if necessary (or to get rid of the warning), a replacement should be provided with `\texorpdfstring`.

Trying to load font information for `<enc>+<family>`

You find such a message in the transcript file whenever \LaTeX tries to load an `.fd` file for the encoding/family combination `<enc>/<family>`.

Unable to redefine math accent `<accent>` `amsmath`

This warning is rare, but it may be issued when loading the `amsmath` package with nonstandard mathematical fonts.

Underfull `\hbox` (badness `<number>`) `<somewhere>` \TeX

\TeX was forced to build a horizontal box (e.g., the line of a paragraph or a `\makebox`) of a certain width, and the white space within that box had to stretch more than it was designed to do (i.e., stretched more than 100% of the available plus parts in stretchable spaces). Internally, this situation is expressed by a badness value greater than 100; a value of 800 means that twice the total stretchability was used to produce the required width.¹

Whether such an underfull box actually presents a noticeable problem is something that you may have to check visually in the produced output. If the badness is 10 000, the box can be arbitrarily bad. Because \TeX 's value for infinity is quite low, it might mean that \TeX has favored one very bad line over several bad but still acceptable lines that appear in succession. In that case, using `\emergencystretch` can help you; see Section 3.1.

The limit of badness values above which such warnings are shown is controlled by the integer parameter `\hbadness`. \LaTeX 's default is 1000, so warnings appear only for really bad boxes. If you want to produce an important document, try a more challenging value, such as `\hbadness=10`, to find out how many lines \TeX really considers imperfect.

Note that the warning always talks about `\hbox`, regardless of the actual box construct used in the source, because it is directly generated by \TeX . The location where the problem occurred is indicated by `<somewhere>`, which is one of the following four possibilities:

detected at line `<line number>` \TeX

An explicitly constructed box (construction ending at line `<line number>` in the source) has the problem — for example, a `\makebox` with an explicit width argument or some other \LaTeX construct that builds boxes.

¹The exact formula is $\min(100r^3, 10000)$ where r is the ratio of “stretch used” to “stretch available”, unless there is infinite stretch present (e.g., introduced by a command like `\hfill`), in which case the badness is zero.

has occurred while \output is active TeX

TeX was in the process of building a page and encountered the problem while attaching running headers and footers and the like. Because this is an asynchronous operation, no line number is given. Look at the page generated closest to where the warning was issued to determine whether it warrants manual correction.

in alignment at lines *<line numbers>* TeX

The box is part of a `tabular` or some math alignment environment. The *<line numbers>* give you the source position of the whole alignment structure, because by the time TeX encounters the problem, it no longer has a way to relate it back to the source in more detail.

in paragraph at lines *<line numbers>* TeX

The underfull box is due to a badly spaced line in the paragraph (source line numbers given as *<line numbers>*). The additional symbolic display of the line in question should help you to pinpoint the problem.

Underfull \vbox (badness *<number>*) *<somewhere>* TeX

TeX was forced to build a vertical box (e.g., a `\parbox` or a `minipage`) of a certain height, and the vertical space in that box had to stretch more than it was supposed to; see the discussion of badness and stretchability in the description of the “Underfull \hbox...” warning. You can suppress all warnings for badness values below a certain limit by setting `\vbadness=<value>`. Then TeX issues warnings only for boxes with a badness larger than *<value>* (the default is 1000). The *<somewhere>* indicates the origin of the problem and can be one of the following cases:

detected at line *<line number>* TeX

The box was explicitly constructed (the *<line number>* points to the end of the box construction), and there is not enough stretchable space available. For example,

```
\parbox[c][2in][s]{4cm}{A test}
```

would produce this warning because the box should be 2 inches high and the contents should fill this height (argument `[s]`), but there is nothing stretchable available — for instance, something like `\par\vfill` between the two words. See Appendix A.3.2 for details on paragraph boxes.

has occurred while \output is active TeX

In the most frequent case, the space on the current page needed stretching beyond acceptable limits in TeX’s eyes. Whether this is visually a real problem depends on many factors, such as the type of spaces on the page. For example, a large stretch in front of a heading is usually less severe than a spaced-out list. Thus, the best advice is to check such pages manually. Often, `\enlargethispage` or `\pagebreak` will help.

If the problem appears surprisingly often, then the spacing parameters for lists, paragraphs, and headings should be examined to see whether they are too rigid (see Chapters 2 to 5). Also check whether the `\textheight` corresponds to an integral number of text lines; see the discussion on page →I 369.

in alignment at lines *<line numbers>* TeX

This warning should not arise with standard L^AT_EX but can occur in some specialized applications. In such a case, use *<line numbers>* to identify the source lines in your document.

Undo math alphabet allocation in version *<version>*

Once the number of math alphabet allocations has reached its allowed limit in a math *<version>*, any further allocation is undone at the end of the formula so that it can be reused differently in later formulas. The message is shown when such deallocation is happening. See page →I 681 for details.

Unused global option(s): [*<option list>*]

Some of the options specified on `\documentclass` have been used by neither the class nor any package in the preamble. A likely reason is that the names of the options have been misspelled. Also note that some packages do not react to global options, but only to those explicitly specified when loading the package. See Appendix A.6 for details.

warning (pdf backend): unreferenced destination with LuaTeX only
name '*<name>*'

Unicode engines

A Lua_TE_X engine warning that a referenced hyperlink destination is missing (the text is somewhat incorrect; the destination, not the link is missing). See the corresponding pdf_TE_X warning on page 758 for more details.

warning (pdf backend): ignoring duplicate destination LuaTeX only
with the name '*<name>*'

Unicode engines

A Lua_TE_X engine warning that two targets for hyperlinks (“destinations”) have the same name. See the corresponding pdf_TE_X warning on page 758 for more details.

Writing file '*<file>*'

This informational message is produced by both the `filecontents` and the `filecontents*` environment when they write a *<file>* that is definitely not yet on the system.

Writing or overwriting file '*<file>*'

In contrast to the previous informational message, the `filecontents` and the `filecontents*` environments show this message as a warning message when

they write a *<file>* that already exists (somewhere) on the system and they are used with the `force` or `overwrite` key and therefore might overwrite it.

Writing text ‘*<text>*’ before `\end{<env>}` as last line of *<file>*

This warning is issued by the `filecontents` or `filecontents*` environment when it detects textual material directly preceding the `\end` tag.

You have more than once selected the attribute ‘*<attrib>*’ babel
for language *<lang>*

This message is displayed if the same attribute is entered more than once in the second argument of `\languageattribute`; only the first occurrence triggers the activation of the attribute.

You have requested *<package or class>* ‘*<name>*’,
but the *<package or class>* provides ‘*<alternate name>*’

You requested loading of *<name>* via `\usepackage` or `\RequirePackage` (in the case of a package) or via `\documentclass` or `\LoadClass` (in the case of a class), but the package or class provides a variant of the original with the internal name *<alternate name>*. Unless this was a typo by the package or class provider, it means that your installation has a package or class variant that is likely to behave differently from the original. Thus, your document may be formatted differently when processed on another installation. Whether this is the correct behavior is something you need to investigate by looking at the package or class in question.

Specifying a relative or absolute path name also triggers this warning as a side effect.

You have requested release ‘*<date>*’ of LaTeX,
but only release ‘*<old date>*’ is available

A `\NeedsTeXFormat` command has requested a L^AT_EX release of at least *<date>*, but the date of your format is *<old date>*. Usually, such a request is made to ensure that a certain feature of the L^AT_EX format is available, so it is likely that your document will produce additional errors or strange formatting later. Update to a more recent version of L^AT_EX.

You have requested, on line *<num>*, version ‘*<date>*’ of *<name>*,
but only version ‘*<old date>*’ is available

A class or package was required to have a date not older than *<date>*, but the version on your installation is from the date *<old date>*. Update the class or package in question.

B.4 T_EX and L^AT_EX commands for tracing

In this section we discuss tools and techniques for tracing and for displaying status information — for example, finding out why something is strangely spaced on the page or why your own command definition does the wrong thing.

B.4.1 Displaying command definitions and register values

In many situations it is useful to get some information about \LaTeX 's current internals, the precise definitions of commands, the values of registers, and so on. For example, if the use of `\newcommand` reports that the command to be defined is already defined, you may want to know its current definition to ensure that you do not redefine an important command.

*Displaying
command definitions*

For this purpose \TeX offers the command `\show`, which displays the definition of the token following it and then stops and displays a question mark while waiting for user intervention. For example, after defining `\xvec` as in Example A-1-5 on page 626, we can display its definition as follows:

```
\newcommand\xvec[1]{\ensuremath{x_1,\ldots,x_{#1}}}  
\show\xvec
```

This produces the following output on the terminal and in the transcript file:

```
> \xvec=\long macro:  
#1->\ensuremath {x_1,\ldots ,x_{#1}}.  
1.6 \show\xvec  
  
?
```

The first line, which starts with `>`, shows the token being displayed (`\xvec`) and gives its type (`\long macro`), indicating that `\xvec` is a macro that accepts `\par` commands in its argument; in other words, this macro was defined with `\newcommand` rather than `\newcommand*`.

The second line shows the argument structure for the command (up to `->`), revealing that the command has one argument (`#1`). Note that while the argument on the `\newcommand` declaration was indicated with `[1]`, it is now shown differently. The rest of the line — and possibly further lines, if necessary — shows the definition part. The code is terminated with a period that is not part of the definition but helps to identify stray spaces at the end of the definition, if any.

Note that the code display is normalized. Thus, after a command that would swallow subsequent spaces, you see a space regardless of whether a space was coded in the original definition.

Following the display of the definition, the source line (including the line number in the input file) is shown. Then \LaTeX stops with a question mark. To continue, you can press Enter. Alternatively, you can type `h` to see what other possibilities are available.

Not all commands produce such easily understandable output. Assume that you try to display a command that was defined to have an optional argument, such as `\lvec` as defined in Example A-1-6 on page 626:

```
\newcommand\lvec[2][n]  
{\ensuremath{\#2_1+\cdots + \#2_{\#1}}}  
\show\lvec
```

In that case you get this result:

```
> \lvec=macro:
->\@protected@testopt \lvec \lvec {n}.
```

Apparently, the `\lvec` command has no arguments whatsoever (they are picked up later in the processing). And something else is strange in this output: what is `\lvec`? Is it the command `\` followed by the letters `lvec`, or is it a strange command `\lvec` that has two backslashes as part of its name? It is actually the latter, though there is no way to determine this fact from looking at the output of the `\show` command. Such strange command names, which cannot be generated easily by the user, are sometimes used by L^AT_EX internally to produce new command names from existing ones using `\csname` and `\endcsname` and other low-level mechanisms of T_EX.

So what should you do if you want to see the definition of `\lvec`? It should be clear that writing `\show` in front of such a command does not work, because in normal situations T_EX sees `\` and thinks that it is the command to “show”. Until recently all you could do was use unwieldy low-level methods such as

*Displaying internal
commands with
strange names*

```
\expandafter\show\csname \string\lvec \endcsname
```

Technically, what happens here is that a command name is generated from the tokens between `\csname` and `\endcsname`. Inside that construct, the `\string` command turns the command `\lvec` into a sequence of characters starting with a backslash that no longer denotes the start of a command. This is why the resulting command name contains two backslashes at the beginning. The `\expandafter` command delays the evaluation of the following `\show` command so that `\csname` can perform all of its work before `\show` is allowed to look at the result.¹

That’s quite a mouthful of low-level T_EX, but in an emergency it may prove helpful to know about the `\csname` trick. However, starting with the 2020 release, L^AT_EX now offers `\ShowCommand` as an improved replacement for `\show`. If you write

```
\ShowCommand\lvec
```

then this produces the following output:

```
> \lvec=robust macro:
->\@protected@testopt \lvec \lvec {n}.

> \lvec=\long macro:
> default #1=n.
[#1]#2->\ensuremath {#2_1+\cdots + #2_{#1}}.
<recently read> }
```

As you can see, the first part is similar to the result from `\show`, but `\ShowCommand` recognizes that `\lvec` is a robust command and more importantly that it also needs

¹Alternatively, you can use `\ExpandArgs{c}\show{\string\lvec}`, but that is not really better.

to show us its internal definition, i.e., replacement for `\lvec`. It even tells us that `#1` is an optional argument with a default of `n`.¹

*Detecting a primitive
command*

`\ShowCommand` can be given any command name as its argument, but it offers maximum details only with commands that have been defined with higher-level \TeX declarations such as `\newcommand`, `\NewDocumentCommand`, etc. For commands that are part of the \TeX engine (so called primitive commands) or defined with a low-level `\def`, it gives you the same result as `\show`. If the command examined is a built-in primitive command, then you get output like the following:

```
> \relax=\relax.
<argument> \relax

1.10 \ShowCommand \relax
```

i.e., a primitive command shows up as being equal to itself.

*Displaying
register values*

The commands `\show` and `\ShowCommand` are useful for learning about commands and their definitions or finding out if something is a primitive of \TeX . However, they do not help in finding the current values of length or counter registers. For example,

```
\show\parskip \show\topmargin \show\topsep
```

gives us the following information:

```
> \parskip=\parskip.
1.5 \show\parskip
\show\topmargin \show\topsep
?
> \topmargin=\dimen109.
1.5 \show\parskip \show\topmargin
\show\topsep
?
> \topsep=\skip29.
1.5 \show\parskip \show\topmargin \show\topsep
```

From the above we can deduce that `\parskip` is a \TeX primitive (the fact that it is a rubber length is not revealed), that `\topmargin` is actually the `\dimen` register (i.e., a rigid length) with register number 109, and that `\topsep` is the `\skip` register (a rubber length) with number 29.

If we want to know the value of any such register, we need to deploy a different \TeX primitive, called `\showthe` instead of `\show` or `\ShowCommand`, which gives us the following output on the terminal and also proves that `\parskip` is, indeed, a rubber length (but only because it has a nonzero plus component):

```
> 0.0pt plus 1.0pt.
1.5 \showthe\parskip
```

¹`\ShowEnvironment{env}` is a comparable command for environments. It displays both the `\begin{env}` and the `\end{env}` code of the environment in the style of `\ShowCommand`.

Using `\showthe` in this way allows us to display the values of the length registers allocated with `\newlength` and of internal T_EX registers such as `\baselineskip` and `\tolerance`. What we cannot display directly with it are the values of L^AT_EX counters allocated with `\newcounter`. For this we have to additionally deploy a `\value` command that turns a L^AT_EX counter name into a form that is accepted by `\showthe`. For example,

L^AT_EX counters need special handling

```
\showthe\value{footnote}
```

would show the current value of the footnote counter on the terminal.

Instead of displaying the meaning of a macro or the value of a register on the terminal, you can alternatively typeset this kind of data by using `\meaning` instead of `\show` and `\the` instead of `\showthe`. The output is slightly different: the name of the token is not shown by `\meaning`; instead, only its type and “meaning” are presented. Compare the next example with the output shown earlier in this section:

Typesetting command definitions or register values

<pre>\long macro:#1->\ensuremath {x_1,\ldots ,x_{#1}} 0.0pt plus 1.0pt 16.0pt 8.0pt plus 2.0pt minus 4.0pt footnote=0</pre>	<pre>\newcommand\xvec[1]{\ensuremath{x_1,\ldots ,x_{#1}}}\ttfamily\small % use smaller typewriter \raggedright \meaning\xvec \par \the\parskip\par \the\topmargin \par \the\topsep \par footnote=\the\value{footnote}</pre>
--	---

B-4-1

If displaying command definitions or register values is insufficient for determining a problem, you can alternatively trace the behavior of the commands in action; see Section B.4.5 on page 781.

B.4.2 Diagnosing page-breaking problems

Once in a while L^AT_EX produces unexpected page breaks or shows some strange vertical spaces and you would like to understand where they are coming from or what precise dimensions are involved. For these tasks, T_EX offers a few low-level tracing tools.

Symbolic display of the page contents

If you specify `\showoutput` somewhere in your document, T_EX displays (starting with the current page) symbolic representations of complete pages on the terminal and the transcript file. This generates a large amount of output, of which we show some extracts that have been produced by compiling the first paragraph of this section separately.

As a side effect, the `\showoutput` command also produces symbolic displays of overfull boxes. Tracing ends at the next closing brace or environment. Thus, to see the output for full pages, you have to place the command into the preamble, or at least ensure that the page break happens before the next group ends.

Side effect of \showoutput

Every page output starts with the string Completed box being shipped out followed by the current page number in brackets. Then you get many lines showing the boxes that make up the page, starting with a `\vbox` (vertical box) and its sizes in

pt containing the whole page. To indicate that something is the contents of a box, everything inside is recursively indented using periods instead of blanks. Spaces, even if they are rigid, are indicated by the keyword `\glue` (see line 3 or 6); stretchable space has some plus and/or minus components in its value, as we see later. Whether it is a horizontal or a vertical space is determined by the box in which this space is placed. For example, the `\glue` of 16.0pt on line 3 is a vertical space that came from `\topmargin`; see also Example B-4-1 on the preceding page. In the extract you also see an empty `\vbox` of height 12pt (lines 5 to 7), which is the empty running header, followed in line 8 by the space from `\headsep` (25pt), followed by the box containing the text area of the page starting at line 10. Lines 15 and following show how individual characters are displayed; here `\T1/cmr/m/n/10` indicates the font for each character. The `\glue` in between (e.g., line 19) marks an interword space with its stretch and shrink components.

```

```

As a second example from a page trace, we show the symbolic display of the structures near a line break. You see the space added by \TeX at the right end of a text line (`\rightskip` on line 5) and the box containing the line. Thus, line 6 is outdented again. It contains a symbolic representation for the costs to \TeX to break after this line, indicated by the command `\penalty`. The actual value here is due to the value of the `\clubpenalty` parameter.¹ This is followed in line 7 by the vertical space

¹The penalty to break after the first line in a paragraph is given by the integer parameter `\clubpenalty`; the cost for breaking before the last line by `\widowpenalty`. Both default to 150;

added between the lines, computed by T_EX by taking the value of `\baselineskip` and subtracting the depth of the previous line box and the height of the following line box, which starts at line 8.

```

1 ....\T1/cmr/m/n/10 s
2 ....\T1/cmr/m/n/10 o
3 ....\T1/cmr/m/n/10 m
4 ....\T1/cmr/m/n/10 e
5 ....\glue(\rightskip) 0.0
6 ... \penalty 150
7 ... \glue(\baselineskip) 2.96054
8 ... \hbox(6.8872+1.94397)x345.0, glue set 0.55421
9 ....\T1/cmr/m/n/10 s
10 ....\T1/cmr/m/n/10 t

```

As a final example, we look at some part of the symbolic page output produced from a line like this:

```
\begin{itemize} \item test \end{itemize} \section{Test}
```

The particular part of interest is the one generated from `\end{itemize}` and `\section{Test}`. What we see here (lines 1 to 7) is a curious collection of `\glue` statements, most of which cancel each other, intermixed with a number of `\penalty` points:

```

1 ... \penalty -51
2 ... \glue 10.0 plus 3.0 minus 5.0
3 ... \glue -10.0 plus -3.0 minus -5.0
4 ... \penalty -300
5 ... \glue 10.0 plus 3.0 minus 5.0
6 ... \glue -10.0 plus -3.0 minus -5.0
7 ... \glue 15.0694 plus 4.30554 minus 0.86108
8 ... \glue(\parskip) 0.0 plus 1.0
9 ... \glue(\parskip) 0.0
10 ... \glue(\baselineskip) 8.12001
11 ... \hbox(9.87999+0.0)x345.0, glue set 290.70172fil

```

These lines are generated from various `\addpenalty` and `\addvspace` commands issued; for example, lines 1 and 2 are the penalty and the rubber space added by `\end{itemize}`. The `\section` command then adds a breakpoint to indicate that the place before the section is a good place to break a page (using `\@secpenalty` with a value of `-300`). In fact, the break should be taken before the `\glue` from line 2, or else there would be a strange space at the bottom of that page. As it is technically impossible to remove material from the vertical galley, `\addpenalty` uses the trick to back up by adding a negative space (line 3), adding the penalty (line 4),

that is, they slightly discourage a break.

and then reissuing the `\glue` (line 5). In lines 6 and 7, the same method is used by `\addvspace` to add the vertical space before the heading.

Lines 8 to 10 are added by \TeX when placing the actual heading text (line 11) into the galley. Note that technically the heading is considered a “paragraph”, so `\parskip` is added. This is the reason why enlarging this parameter requires careful planning. The same care should be taken when adjusting other parameters (like the one added on line 7).

In fact, you see `\parskip` being added twice, in one case with a value of 0.0. The reason for this curiosity is that these days \TeX trial-starts the paragraph to execute the `para/before` hook and then stops and restarts the paragraph again. Obviously, a real `\parskip` should be added only once, but because \TeX always adds the current value of `\parskip` whenever it starts a paragraph, \TeX locally sets it to 0pt on one of the occasions, and this is what we see.

Tracing page-break decisions

If you want to trace page-breaking decisions, \TeX offers symbolic information that you can turn on by setting the internal counter `\tracingpages` to a positive integer value:

```
\tracingonline=1 \tracingpages=1
```

Setting `\tracingonline` to a positive value ensures that the tracing information appears not only in the transcript file (default), but also on the terminal.

Processing the previous paragraph starting with “If you want to...” as a separate document, we get the following lines of tracing information:

```
1  %% goal height=522.0, max depth=4.0
2  % t=10.0 g=522.0 b=10000 p=150 c=100000#
3  % t=22.0 g=522.0 b=10000 p=150 c=100000#
4  % t=55.0 plus 4.0 g=522.0 b=10000 p=-51 c=100000#
5  % t=77.0 plus 8.0 g=522.0 b=10000 p=300 c=100000#
6  % t=89.0 plus 8.0 g=522.0 b=10000 p=0 c=100000#
7  % t=90.94397 plus 8.0 plus 1.0fil g=522.0 b=0 p=-10000 c=-10000#
```

The first line starting with two percent signs shows the target height for the page (i.e., 522pt in this case), which means 43 lines at a `\baselineskip` of 12pt with 2pt missing, because the skip to position the first base line, `\topskip`, has a value of 10pt. If the goal height does not result in an integral number of lines, problems like underfull `\vboxes` are likely to happen.

*Target size of
a break*

The remaining lines, starting with one percent sign, indicate a new potential page-break position that \TeX has considered. You can interpret such lines as follows: `t=` shows the length of the galley so far and, if the galley contains vertical rubber spaces, their total amount of stretch and shrink. Line 4, for example, shows that in the layout of this book verbatim displays have an extra space of 10pt plus a stretch of 4pt (the verbatim lines are typeset in a smaller font with only 11pt of `\baselineskip`) and the same amount is added between lines 4 and 5.

The `g=` specifies the goal height at this point. This value changes only if objects like floats have reduced the available space for the galley in the meantime. *Page goal height*

With `b=`, T_EX indicates the badness of the page if a break would be taken at this point. The badness is calculated from the factor by which the available stretch or shrink in `t=` must be multiplied to reach the goal height given in `g=`. In the example the page is barely filled, so it is always 10000 (infinitely bad), except for line 7, where, due to the added `fil` stretch, the page is suddenly considered optimal (`b=0`). *Page badness*

With each breakpoint T_EX associates a numerical `\penalty` as the cost to break at this point. Its value is given by `p=`. For example, it is not allowed to break directly before the verbatim display, which is why there is a large increase in `t=` between lines 3 and 4. On the other hand, a break after the display is given a bonus (`p=-51`). Line 5 shows that breaking after the first line of the two-line paragraph fragment following the verbatim text is considered bad (`p=300`), because it would result in both a club and a widow line (`\clubpenalty` and `\widowpenalty` each have a value of 150, and their values are added together). *Break penalty*

Finally, `c=` describes the calculated cost to break at this breakpoint, which is derived from a formula taking the badness of the resulting page (`b=`) and the penalty to break here (`p=`) into account. T_EX looks at these cost values and eventually breaks at the point with minimal cost. If the line ends in `#`, then T_EX thinks that it would be the best place to break the page after evaluating all breakpoints seen so far. In the example, all lines show this `#`—not surprising, given that T_EX considers all but the last breakpoint to be equally bad. *Costs of a page break*

If the pages would become too full if a break is taken at a particular breakpoint, then T_EX indicates this fact with `b=*`. At this point T_EX stops looking for other breakpoints and instead breaks the page at the best breakpoint seen so far.

For additional details on the output produced by these low-level display devices, consult [84, p.112].

B.4.3 Diagnosing and solving paragraph-breaking problems

If T_EX is unable to find a suitable set of points at which to break a paragraph into lines, it produces, as a last resort, one or more lines that are “overfull”. For each of them you get a warning on the screen and in the transcript file, such as

```
Overfull \hbox (5.10907pt too wide) in paragraph at lines 3778--3793
\T1/hlh/m/n/10 showing you a sym-bolic dis-play of the text line and the
line num-ber(s) of the paragraph|
```

showing you a symbolic display of the text line and the line number(s) of the paragraph containing it. If you look at the symbolic display, you can easily diagnose that the problem is T_EX’s inability¹ to hyphenate the word “paragraph”. To explicitly flag such lines in your document, you can set the parameter `\overfullrule` to a positive value. For the present paragraph it was set to 5pt, producing the blob of ink

The black blob of ink above is deliberate

¹T_EX is, in fact, perfectly capable of hyphenating “para-graph”; for the example, we explicitly prevented it from doing so. The paragraph would have been perfect otherwise.

clearly marking the line that is overfull. The standard document classes enable this behavior with the option `draft`. On the other hand, you may not mind lines being only slightly overfull. In that case you can change the parameter `\hfuzz` (default `0.1pt`); only lines protruding by more than the value of `\hfuzz` into the margin are then reported.

If \TeX is unable to break a paragraph in a satisfying manner, the reasons are often hyphenation problems (unbreakable words, as in the above example), problems with the parameter settings for the paragraph algorithm, or simply failure of the text to fit the boundary conditions posed by the column measure or other parameters, together with aesthetic requirements like the allowed looseness of individual lines. In the latter case the only remedy is usually a partial rewrite.

Dealing with hyphenation problems

With the relevant hyphenation patterns loaded, \TeX is able to do a fairly good job for many languages [121]. By using `microtype`, described in Section 3.1.3 on page 126, this can be improved even further, because the font compression and expansion deployed by `microtype` reduce the number of hyphenations considerably.¹

However, it usually does not find all potential hyphenation points, so sometimes one has to assist \TeX in this task. To find out which hyphenation points in words like “laryngologist” are found by \TeX , you can place such words or phrases in the argument of the command `\showhyphens`:

```
\showhyphens{laryngologist laryngopharyngeal}
```

Running this statement through \LaTeX gives you some tracing output on the terminal and in the transcript file. The hyphenation points determined by \TeX are indicated by a hyphen character:

```
[ ] \OT1/cmr/m/n/10 laryn-gol-o-gist laryn-gopha-ryn-geal
```

If you want to add the missing hyphenation points, you can specify all hyphenation points for one word locally in the text using `\-`, for example,

```
la\ryn\gol\o\g\o-gist la\ryn\go\pha\ryn\ge\al
```

Alternatively, you can use a `\hyphenation` declaration in the preamble:

```
\hyphenation{la-ryn-gol-o-gist la-ryn-go-pha-ryn-ge-al}
```

The latter technique is particularly useful when you detect a wrong hyphenation or often use a word for which you know that \TeX misses important hyphenation points. Note that such explicit specifications tell \TeX how to hyphenate words that are exactly in the form given. Thus, the plural “laryngologists” would be unaffected unless you specify its hyphenation points as well.

¹This is why we generally recommend loading this package in documents that are set justified.

The `\hyphenation` declarations apply to the current language, so if a document uses several languages — for example, by using the methods provided by the `babel` system — then you need to switch to the right language before issuing the relevant declarations.

showhyphenation, lua-check-hyphen — Display hyphenation points with LuaT_EX

Unicode engines

The two packages described here are unfortunately available only with LuaT_EX, because they make use of features not available in any of the other engines. They interface with the paragraph building process and visualize the hyphenation points found by LuaT_EX or collect all words that are finally hyphenated, respectively.

The `showhyphenation` package by Thomas Kelkel helps you resolve cases in which T_EX breaks a paragraph in a bad way, by allowing you to quickly check if T_EX has missed one or the other possible hyphenation.

The `lua-check-hyphen` package by Patrick Gundlach on the other hand writes out all words that are actually hyphenated into a file with the extension `.uhy`. Once your document is in final form, you can look at this file to make sure that there are not any bad hyphenations (either unfortunate ones that you may want to avoid or, worse, some wrong ones that definitely need correcting).

It also offers you to maintain a list of accepted hyphenations in some external file that can be loaded with the option `whitelist` so that you do not have to repeatedly check the same entries over and over again. Both packages are demonstrated in the next example.

This short paragraph demonstrates the usefulness of the packages `showhyphenation` and `check-lua-hyphens`. The first automatically marks all hyphenation points found by the engine with a small triangular mark. The second package writes out all hyphenations that happened in the document into a file with the extension `.uhy`. You can then examine that file to find any issues with the hyphenation and correct them as necessary.

B-4-2

```
\usepackage{showhyphenation}
\usepackage{lua-check-hyphen}
```

This short paragraph demonstrates the usefulness of the packages `\textsf{showhyphenation}` and `\textsf{check-lua-hyphens}`. The first automatically marks all hyphenation points found by the engine with a small triangular mark. The second package writes out all hyphenations that happened in the document into a file with the extension `\texttt{.uhy}`. You can then examine that file to find any issues with the hyphenation and correct them as necessary.

In the example there are two lines ending in a hyphen, and the `.uhy` file, written by `lua-check-hyphen`, shows the following data:

```
automat-ically
hyphen-ations
```

If you do not like the hyphenation of “automatically”, you could then turn to your

document source and add an explicit `\-`, i.e., `auto\~mati\~cally`. Alternatively, you could generally disallow this hyphenation point by specifying an exception with `\hyphenation{au-to-mati-cally}`. Either way, our example paragraph would afterwards be broken differently.

Tracing the paragraph algorithm

Because T_EX uses a global algorithm for optimizing paragraph breaking, it is not always easy to understand why a certain solution was chosen. If necessary, one can trace the paragraph-breaking decisions using the following declarations:¹

```
\tracingparagraphs=1 \tracingonline=1
```

For readers who really want to understand the reasons behind certain decisions, we show some example data with detailed explanations below.

Paragraph tracing produces output that looks somewhat scary. For instance, one of the previous paragraphs generated data that starts like this:

```
1  @firstpass
2  @secondpass
3  []\T1/cmr/m/n/10 The [] dec-la-ra-tions ap-ply to the cur-rent lan-guage, so
4  @ via @@0 b=3219 p=0 d=10436441
```

*Up to three passes
over paragraph
data*

Line 2 says that T_EX has immediately given up trying to typeset the paragraph without attempting hyphenation. This is due to the value of `\pretolerance` being set to 100 in the sources for the book; otherwise, T_EX may have gotten further or even succeeded (in English text quite a large proportion of paragraphs can be reasonably set without hyphenating²). In addition to `@secondpass`, you sometimes see `@emergencypass`, which means that even with hyphenation it was impossible to find a feasible solution and another pass using `\emergencystretch` was tried.³ Line 3 shows how far T_EX had to read to find that first potential line ending that results in a badness of less than $\infty = 10000$. Line 4 gives details about this possible break. Such lines start with a single `@`; the `via` gives the previous breakpoint (in this case `@@0`, which refers to the paragraph start), the line badness (`b=`), the penalty to break at this point (`p=`), and the so-called demerits (`d=`) associated with taking that break (a “cost” that takes into account badness, penalty, plus context information like breaking at a hyphen or the visual compatibility with the previous line).

```
5  @@1: line 1.0 t=10436441 -> @@0
```

In line 5, T_EX informs us that it would be possible to form a very loose first line ending in the breakpoint given by line 3 with a total cost (`t=`) equal to the demerits shown on line 4. This line would be formed by starting at breakpoint `@@0`. The notation `line 1.0` gives the line number being made, and the suffixes `.0`, `.1`, `.2`, `.3`, respectively, stand for very loose, loose, decent, and tight interword spacing in the line. This classification is important when comparing the visual compatibility of consecutive lines.

¹These parameters are also turned on by a `\tracingall` command, so you may get many lines of paragraph tracing data, even if you are interested in something completely different.

²For the *L^AT_EX Companion* with its many long command names in the text, this is less likely.

³For this to happen, `\emergencystretch` needs to have a positive value. See also the discussion in Section 3.1.

T_EX now finds more and more potential line breaks, such as after “if” in line 6 and after “a” in line 9. Each time T_EX tells us what kind of lines can be formed that end in the given breakpoint. If `b=*` appears anywhere in the trace data, it means that T_EX could not find a feasible breakpoint to form a line and had to choose an infeasible solution (i.e., one exceeding `\tolerance` for the particular line).

```

6  if
7  @ via @@0 b=1087 p=0 d=1213409

```

By hyphenating the word `doc-u-ment`, it finds two more breakpoints (lines 12 and 15). This time you see a penalty of 50 — the value of the parameter `\hyphenpenalty` (breaking after a hyphen) — being attached to these breaks. Line 15 is the last breakpoint that can be used to produce the first line of the paragraph. All other breakpoints would produce an overfull line. Hence, the next tracing line again shows more text; none of the potential breakpoints therein can be used because they would form a second line that exceeds `\tolerance`.

```

18 ment uses sev-eral languages\Dash for ex-am-ple, by us-ing the meth-
19 @\discretionary via @@1 b=1194 p=50 d=1452116
20 @\discretionary via @@2 b=2875 p=50 d=8325725
21 @@6: line 2.0- t=9539134 -> @@2

```

Here the breakpoint can be used to form a second line in two different ways: by starting from breakpoint `@@1` (line 19) or by starting from breakpoint `@@2` (line 20). If we compare just these two solutions to form the second line of the paragraph, then the first would be superior: it has a badness of 1194, whereas the second solution has a badness of 2875, which results in a factor of 5 in “costs” (`d=`). Nevertheless, T_EX considers the second break a better solution, because a first line ending in `@@1` is so much inferior to a line ending in `@@2` that the total cost for breaking is less if the second alternative is used. T_EX therefore records in line 21 that the best way to reach the breakpoint denoted by line 18 is by coming via `@@2` and results in a total cost of `t=9539134`. For the rest of the processing, T_EX does not need to know that there were several ways to reach `@@6`; it just needs to record the best way to reach it.

More precisely, T_EX needs to record the best way to reach a breakpoint for any of the four types of lines (very loose, loose, decent, tight), because the algorithm attaches different demerits to a solution if adjacent lines are visually incompatible (e.g., a loose line following a tight one). Thus, later in the tracing (lines 22–40 are not shown), we get the following output:

```

41 by
42 @ via @@3 b=19 p=0 d=10841

```

```

43 @ via @@4 b=9 p=0 d=361
44 @ via @@5 b=42 p=0 d=2704
45 @@10: line 2.1 t=5325 -> @@5
46 @@11: line 2.2 t=2961 -> @@4

```

This output indicates that there are three ways to form a line ending in “by”: by starting from @@3, @@4, or @@5. A line with a badness of 12 or less is considered decent (suffix .2); a line stretching, but with a badness not higher than 100, is considered loose (suffix .1). So here T_EX records two feasible breakpoints for further consideration — one going through @@5 and one going through @@4.

Which path through the breakpoints is finally selected can be decided only when the very end of the paragraph is reached. Thus, any modification anywhere in the paragraph, however minor, might make T_EX decide that a different set of breakpoints forms the best solution to the current line-breaking problem, because it produces the lowest total cost. Due to the complexity of the algorithm, minor modifications sometimes have surprising results. For example, the deletion of a word may make the paragraph a line longer. This may happen because T_EX decides that using uniformly loose lines, or avoiding hyphenation of a word, is preferable to some other way to break the paragraph. Further details, describing all parameters that influence the line-breaking decisions, can be found in [84, p.98]. If necessary, you can force breakpoints in certain places with `\linebreak` or prevent them with `\nolinebreak` or by using `~` in place of a space. Clearly, choices in the early parts of a paragraph are rather limited, and you may have to rewrite a sentence to avoid a bad break. However, later in a paragraph nearly every potential break becomes feasible, being reachable without exceeding the specified `\tolerance`.

Shortening or lengthening a paragraph

Another low-level tool that can be used to help with paragraph line breaking or more often with pagination problems, is the internal counter `\looseness`. If you set it to a nonzero integer n , then T_EX tries to make the next paragraph n lines longer (n positive) or shorter (n negative), while maintaining all other boundary conditions (e.g., the allowed `\tolerance`). For example on page 781, we have artificially shortened the paragraph starting in the following way:

```

\looseness=-1
Finally, you can direct \TeX{} to step through your files ... as well.

```

Without this adjustment T_EX would have preferred to place the final “well.” on a line by itself. Now the paragraph is set a bit too tight for T_EX’s taste, but the overall result is noticeably better.

Setting the value of `\looseness` is not guaranteed to have any effect. Shortening a paragraph is more difficult for T_EX than lengthening it, because interword spaces have a limited shrinkability that is small in comparison to their normal stretchability. The best results are obtained with long paragraphs having a short last line. Consequently, extending a paragraph works best on long paragraphs with a last line that is already nearly full, though you may have to put the last words of the paragraph together in an `\mbox` to ensure that more than one word is placed into the last line. A more detailed discussion of this approach is given in Section 5.6.8 on page →I 427.

B.4.4 Other low-level tracing tools

T_EX offers a number of other internal integer parameters and commands that can sometimes help in determining the source of a problem. They are listed here with a short explanation of their use.

We already encountered `\tracingonline`. If it is set to a positive value, all tracing information is shown on the terminal; otherwise, most of it is written only to the transcript file. This parameter is automatically turned on by `\tracingall`. *On-line tracing*

With `\tracingoutput`, tracing of page contents is turned on. What is shown depends on two additional parameters: `\showboxdepth` (up to which level nested boxes are displayed) and `\showboxbreadth` (the amount of material shown for each level). Anything exceeding these values is abbreviated using `etc.` or `[]` (indicating a nested box) in the symbolic display. The L^AT_EX command `\showoutput` sets these parameters to their maximum values and `\tracingoutput` to 1 so that you get the most detailed information possible. The `\showoutput` command is automatically called by `\tracingall`.

To see the contents of a box produced with `\sbox` or `\savebox`, you can use the T_EX command `\showbox`: *The contents of boxes*

```
\newsavebox\testbox \sbox\testbox{A test}
{\tracingonline=1 \showbox\testbox }
```

However, the result is fairly useless if you do not adjust both `\showboxdepth` and `\showboxbreadth` at the same time:

```
> \box52= []
```

OK.

Hence, a better strategy is to use L^AT_EX's `\showoutput`:

```
{\showoutput \showbox\testbox }
```

Notice the use of braces to limit the scope of `\showoutput`. Without the braces you would see all of the following page boxes, which might not be of much interest. The same type of symbolic display as discussed in Section B.4.2 is displayed on the terminal:

```
> \box52=
\hbox(6.83331+0.0)x27.00003
.\OT1/cmr/m/n/10 A
.\glue 3.33333 plus 1.66498 minus 1.11221
.\OT1/cmr/m/n/10 t
.\OT1/cmr/m/n/10 e
.\OT1/cmr/m/n/10 s
.\OT1/cmr/m/n/10 t
```

OK.

If you add `\scrollmode` or `\batchmode` before the `\showbox` command, \TeX does not stop at this point. You can then later study the trace in the transcript.

*Local
restores*

To see what values and definitions \TeX restores when a group ends, you can set `\tracingrestores` to a positive value. It is automatically turned on by the command `\tracingall`.

\TeX 's stack of lists

With `\showlists` you can direct \TeX to display the stack of lists (vertical, horizontal) that it is currently working on. For instance, putting `\showlists` into the footnote¹ of the present paragraph, we obtain the following output in the `.log` file:

```
### horizontal mode entered at line 3066 []
spacefactor 1000
### internal vertical mode entered at line 3066
prevdepth ignored
### horizontal mode entered at line 3060 []
spacefactor 1000
### vertical mode entered at line 0
### current page: []
total height 514.70349 plus 26.0 minus 2.0
goal height 522.0
prevdepth 1.70349
```

Here the text of the footnote started at line 3066, and the `\spacefactor` was set to 1000 at its beginning. The footnote itself was started on that same line, contributing the “internal vertical mode”, and \TeX correctly disregarded the outer value of `\prevdepth`. The footnote was part of a paragraph that started on source line 3060, which in turn was embedded in a vertical list that started on line 0, indicating that it is the main vertical galley.

Finally, the output shows some information about the current page list that is being built, including its current height, its target height, and the value of `\prevdepth` (i.e., the depth of the last line on the page at the moment).

Because of the default settings for `\showboxbreadth` and `\showboxdepth`, the contents of all lists are abbreviated to `[]`. To get more detail adjust them as necessary or use `\showoutput\showlists` to get the full details.

*Tracing the
processing*

Not very useful on its own, but helpful together with other tracing options, is `\tracingcommands`, which shows all primitives used by \TeX during processing. A related internal integer command is `\tracingmacros`, which shows all macro expansions carried out by \TeX . If set to 2, it also displays the expansion of conditionals. Both parameters are automatically turned on by `\tracingall`.

*Tracing lost
characters*

When everything is set up correctly, it is unlikely that pdf \TeX will ever access a font position in the current font that is not associated with a glyph. However, some commands, such as `\symbol`, can explicitly request any font slot, so it is not impossible.

¹A footnote starts a new vertical list and, inside it, a new horizontal list for the footnote text.

Unicode engines

Unfortunately, the situation in the Unicode engines is worse, because these engines assume that all fonts can typeset *any* Unicode character, which is obviously false. As a result, it is rather likely that, depending on the fonts used in the document, one or the other more uncommon character is unavailable and therefore does not print when requested.

Sadly, T_EX, and by extension the other engines based on it, never considered this event to be an error (which it should have). It merely traces such missing characters by writing unsuspicious transcript entries, and it takes that step only if `\tracinglostchars` is set to a positive value.

More recently most engines have been extended so that you now can get warnings on the terminal (`\tracinglostchars` set to 2) or even errors (value 3). L^AT_EX tries to be helpful by initializing this internal integer to 2. However, especially with Unicode engines we recommend changing this to 3 in the preamble of your documents to avoid undetected missing characters in your documents.

 *Better use the setting `\tracinglostchars = 3` in the preamble*

Finally, you can direct T_EX to step through your files line by line. When setting `\pausing` to 1, each source line is first displayed (suffixed with `=>`). T_EX then waits for instructions regarding what to do with it. Pressing `<Enter>` instructs T_EX to use the line unchanged; anything else means that T_EX should use the characters entered by the user instead of the current line. T_EX then executes and typesets whatever it was passed, displays the next line, and stops again. To continue normal processing you can reply with `\pausing=0`, but remember that this is used in place of the current source line, so you may have to repeat the material from the current source line as well.

Stepping through a document

B.4.5 trace — Selectively tracing command execution

The L^AT_EX command `\tracingall` (inherited from plain T_EX) is available to turn on full tracing. L^AT_EX added `\tracingnone` to turn tracing off again without requiring grouping. There are, however, some problems with this kind of tracing because it turns on all tracing levels, and some parts of L^AT_EX produce enormous amounts of tracing data that is of little or no interest for the problem at hand.

For example, if L^AT_EX has to load a new font, it enters some internal routines of NFSS that scan font definition tables and perform other activities. And 99.9% of the time you are not at all interested in that part of the processing, but just in the two lines before and the five lines after it. Nevertheless, you have to scan through a few hundred lines of output and try to locate the lines you need (if you can find them).

Another example is a statement such as `\setlength\linewidth{1cm}`. With standard L^AT_EX this gives five lines of tracing output. With the `calc` package loaded, however, it results in about sixty lines of tracing data — probably not what you expected and not really helpful unless you try to debug the `calc` parsing routines (which ideally should not need debugging).

To solve this problem, the `trace` package defines a pair of commands, `\traceon` and `\traceoff`, that behave like `\tracingall` and `\tracingnone` except that they selectively turn tracing on and off based on what is being processed.

Another difference between `\traceon` and `\tracingall` is that the latter always displays the tracing information on the terminal, whereas `\traceon` can be directed to write only to the transcript file if you specify the option `logonly`. This is useful when writing to the terminal is very slow (e.g., if running in a shell buffer inside `emacs`).

The `trace` package has a number of internal commands for temporarily disabling tracing. It redefines the most verbose internal \TeX functions so that tracing is turned off while they are executing. For example, the function to load new fonts is handled in this way. If a document starts with the two formulas

```
$a \neq b$    \small $A = \mathcal{A}$
```

then \TeX loads 22 new fonts¹ at this point. Using standard `\tracingall` on that line results in roughly 7500 lines of terminal output. On the other hand, if `\traceon` is used, only 350 lines are produced (mainly from tracing `\small`).

The commands for which tracing is turned off are few and are unlikely to relate to the problem at hand. However, if you need full tracing, you can either use `\tracingall` or specify the `full` option. In the latter case, `\traceon` traces everything, but you can still direct its output exclusively to the transcript file.

¹You can verify this with the `loading` option of the `tracefmt` package.

APPENDIX C

Going Beyond

C.1 Learn \LaTeX — A \LaTeX online course for beginners	784
C.2 Finding information available on your computer	785
C.3 Accessing online information and getting help	787
C.4 Getting all those \TeX files.	789
C.5 Giving back to the community	792

While we certainly hope that your questions have been answered in this book, we know that this cannot be the case for all questions. This appendix tries to help in that unfortunate case.

The first section deals with the fundamental problem that our book (despite being rather large) is not meant for beginners. To make good use of it, you already need some basic knowledge of \LaTeX . If this is missing, then there is a great online course to teach you the foundations.

For questions related to specific packages discussed in the book, it can be helpful to read the original documentation provided with the package. Appendix C.2 suggests ways to find that documentation on your system.

Appendix C.3 then shares how to find online information to research questions that you may have, and how to interact with people in the \TeX community when you experience problems.

This is followed in C.4 by explaining how best to obtain \LaTeX packages that are missing on your installation. It also gives a brief overview of \TeX distributions and \LaTeX services in the cloud.

The final section talks about the community itself and how you can join it to make a difference and keep the ship afloat.

C.1 Learn L^AT_EX — A L^AT_EX online course for beginners

*Worry-free
experimentation in
a browser*

If you are new to L^AT_EX and picked up this book hoping that it also covers the L^AT_EX basics (which it understandably does not, if you look at the current page number) or if you need to refresh your memory on the basics, we recommend that you take a look at the Learn L^AT_EX website at <https://learnlatex.org>, which offers a great online course, teaching you the fundamentals and allowing you to experiment with L^AT_EX online — even without installing the system locally.

*Available in several
languages*

The Learn L^AT_EX project was born out of the desire to provide any easy-to-access approach for L^AT_EX beginners. The site has been designed and implemented by members of the L^AT_EX Project Team, primarily by David Carlisle and Joseph Wright, as well as a larger group of volunteers who helped shape the content and did a marvelous job of translating it to several languages so that the full course is now available in Catalan, English, Español, French, German, Marathi, Portuguese, and Vietnamese — and, who knows — soon perhaps additional languages.

*18 lessons to get
you going*

The curriculum consists of eighteen easy-to-consume lessons with interactive examples and exercises that can be processed and modified (!) in the browser, covering the basics that you need to get started with L^AT_EX and that underpin all the information provided in the current book. The central idea of the site is to get people started with one of the most common L^AT_EX tasks: write some academic document such as an article or report. The topics start with simple L^AT_EX structure, cover things such as including images or building tables, and move on to longer documents and bibliographies. Typesetting mathematics is clearly a core L^AT_EX strength, but here the course remains deliberately lightweight and touches on only a few concepts; it is enough to get you going but certainly not enough to write a complex math paper — the thoughts being that details like those covered in Chapter 11 are better mastered in a second step.

*... more on each
topic*

Each lesson comes with an extra “More on this topic” page that can be bypassed when working through the course for the first time but that offers additional details if you are interested in a particular topic. For example, the lesson on tables focuses on the array package as the fundamental extension to L^AT_EX’s basic tabular environment and explains the main concepts such as the different kinds of column specifiers, how to add rules, and how to merge cells. The “More on this topic” page then goes into styling columns with the help of specifiers, manipulating space between columns, or producing customized rules and much more.

*Recommend this to
new users*

Being closely linked with the L^AT_EX Project Team that maintains and develops L^AT_EX for you, the site is expected to stay up-to-date (in contrast to many other sites sprinkled across the Internet that have been set up with good intentions, but which then sadly declined in quality over the years). By offering a couple of ways to process the examples online (or off-line because the examples are plain text that is easily copied) and by presenting the course in several languages, it provides a low-barrier introduction to learning L^AT_EX. As it stands, it is a great resource for starting with L^AT_EX, and even if you personally have no need for it at your level of experience, it may be good to take a look and see how it functions. There may be a need to convince a colleague or friend to take the first steps with L^AT_EX, and this site may just convince them that L^AT_EX is not too hard to learn and worth the trouble — and for the rest there are books like the one you are currently holding in your hands.

C.2 Finding information available on your computer

When you want to use a \LaTeX package, it would be nice if you could study the documentation without having to remember where the relevant files are located on your \TeX system. Two important command-line tools exist to help you in your search: `kpsewhich` and `texdoc`. The first is most important if you want to study code, while the second helps you to easily find available documentation in your distribution.

C.2.1 `kpsewhich` — Find files the way \TeX does

When \TeX loads files (at least those loaded with `\input` or similar), it uses a special search library named `kpathsea` by Karl Berry that determines where to look and which file to load in case there is more than one with the same name.

The file name loaded is written into the `.log` file so you can find out what was loaded there, but this is not necessarily the most convenient way given that the transcript file contains a lot of other information. It also would not help if you ask yourself the question “which `array.sty` would \LaTeX load if I use `\usepackage{array}`?” unless you first make a test file, run it through \LaTeX , and then look at the transcript.

To help with this, the library is also available as the standalone command-line tool `kpsewhich`. In most cases it is enough to pass it the name of the file you are interested in, e.g., `kpsewhich array.sty`, and it responds with the full path for the file:

```
/usr/local/texlive/2022/texmf-dist/tex/latex/tools/array.sty
```

You can load it into your editor if you want to look at the code. You can also call `kpsewhich` with the option `-all`, in which case it returns

```
/usr/local/texlive/2022/texmf-dist/tex/latex/tools/array.sty
/usr/local/texlive/2022/texmf-dist/tex/latex-dev/tools/array.sty
```

i.e., all files with that name that it knows about.

You may wonder when (if ever) the other files are used by \LaTeX . The answer is it depends on the program name used for running \LaTeX . For example, if you use any of the development formats, e.g., `pdflatex-dev`, the `array` package from the `latex-dev` directory is used, because the search library has different search rules based on the program that is initiating the search. To mimic that with `kpsewhich`, pass it the option `-progrname=<prog>`, and you get the result that would be returned to `<prog>` for the search:

```
kpsewhich -progrname=pdfplatex-dev array.sty
```

would return

```
/usr/local/texlive/2022/texmf-dist/tex/latex-dev/tools/array.sty
```

i.e., the package version for the next \LaTeX release.

If you want to find out where the \LaTeX format file resides that is used by \LaTeX , it is not enough to just specify the name of the format file. You also have to tell `kpsewhich` which engine is loading it, using the option `-engine=<engine>`. Possible engine names are `pdftex`, `xetex`, or `luahtex`. Together with the `-all` option, this is a great help if you receive a “Mismatched LaTeX support files” error; see page 730.

The program offers several other options; a list can be obtained with `-help`, but most of them are needed only for developers who set up a \TeX distribution. The one that may be of interest occasionally is `-debug=32`. This produces detailed tracing output about how `kpsewhich` does its search and where it looks, which can be helpful if \LaTeX seems to be unable to find a file that you know is on your system. The `-debug` option can be given other numeric values to show other aspects of its behavior. For details on that and other features of \TeX ’s search library, take a look at the documentation with `texdoc kpathsea`.

C.2.2 `texdoc`—A command-line interface to local \TeX information

The `texdoc` program has a long history: it started out as a Unix shell script developed in the early nineties by Thomas Esser. The first Lua-based version was then written by Frank Küster with contributions by Reinhard Kotucha. It offered some operating system independence, because Lua, through `LuaTeX`, is available with any \TeX (decent) distribution without the need to install separate programs.

Today’s greatly enhanced version is developed and maintained by Manuel Pégourié-Gonnard and ASAKURA Takuto and the \TeX Live team.

Initially you had to know the exact name of the documentation except for the file extension, so it was quite similar to `kpsewhich` in that regard. The current implementation, however, has a much more general search mechanism that accounts for the fact that many developers use schemes such as `package-doc.pdf`, `package-manual.pdf`, etc., for their documentation. It also has an alias mechanism through which individual documentation files can be associated with some keyword(s) people are likely to search for. For example, the file `interface3.pdf` (the interface documentation for the L3 programming layer) is one of the results if you search for `expl3`. This is managed through a configuration file that is part of the \TeX distribution and regularly updated. You can also have your own configuration file as explained in the program documentation.

Most of the time all you have to do is to pass `texdoc` the name of a package as an argument, e.g., `texdoc fewerfloatpages`, and it replies by opening the (what it thinks) best result in a suitable viewer for you; in this case it would open the file `fewerfloatpages-doc.pdf`.

If this turns out not to be the documentation you have been looking for, your next possibility is to use it with the option `-l`. If you do that, it replies with a list of “useful” documentation files based on your input, and you can then choose one of them to be opened. For example, `texdoc -l array` would return five results: the official package documentation, the (possibly updated) version in the \LaTeX development release, as well as a French translation of the package documentation.

If that is still not what you want, you can use `-s` instead. In that case `texdoc` returns all files it has found, even those that it considered to be a bad match. For

Opening the best result for viewing

Getting a list of “good” results to choose from

Getting a list of “all” results

example, in the case of `array`, you would then get 93 possibilities listed, among them many that have your keyword `array` as part of the name but also some that do not.

There is also the option `-m` (for mixed). It works like `-l`, but if only one result is found, then it opens that immediately for viewing instead of presenting you with a choice list with only one item. The `texdoc` program has a few more options that are helpful only in special circumstances and are not described here. If you want to learn about them, you have to read the program documentation, which you can do by — surprise — executing `texdoc texdoc`.

Using mixed mode

C.3 Accessing online information and getting help

There is a wealth of information available on the Internet, but unfortunately even with good search engines this is not always easy to find nor is it always easy to distinguish good advice from bad. To help you with both, we have selected a few different resources that we think are helpful. Obviously there are several others that are equally good — all we want to express here is that the selection forms a good and reliable starting point for getting your questions answered.

C.3.1 `texdoc.org` — searchable documentation on the Web

The website <https://texdoc.org> works similarly to the `texdoc` utility. It allows you to search for documentation just like you would do with `texdoc`'s `-l` and then choose from among the results, but instead of the command line you use a browser. This is useful if you prefer working with a GUI instead of the command line or if you have installed only a small distribution where a lot of interesting packages are excluded. By using the topic search, this enables you to find material that is not locally available. See also the CTAN catalogue that offers a similar functionality.

C.3.2 Frequently Asked Questions (FAQ) resources

Very valuable resources are the existing Frequently Asked Questions (FAQ) documents. The most important one is probably the \TeX FAQ, available online at <https://texfaq.org>. It is the successor of the UK-TUG FAQ by Robin Fairbairns (1947–2022) and now curated by members of the \LaTeX Project Team, with contributions from a very wide range of other \TeX experts over many years, so it is likely to be reasonably current and accurate.¹

There is also a great document named `visualFAQ.pdf` by Scott Pakin that offers a visual entry point to the \TeX FAQ. It is an innovative new search interface that presents more than a hundred typeset samples of frequently requested document formatting. Any point of interest is marked with a rectangular box (green for tasks you might want to achieve and red for visual errors you might encounter), and clicking on any of them opens the corresponding FAQ entry in the \TeX FAQ. Given that it is more

¹ If you search the Internet, you are likely to come across other FAQ documents on \TeX and \LaTeX in different languages. However, be aware that some of them are no longer maintained and thus are likely to give advice that is a decade or more out of date.

than thirty pages long, it covers a huge number of samples, but of course this also means that it might take you a while to locate one. The document is likely to be part of your installation; try `texdoc visualFAQ`. If not, you can download it from CTAN.

French version

A translation of this document into French by J  r  my Just is also available under the name `visualFAQ-fr.pdf`. The links it contains point to the French FAQ site (<https://faq.gutenberg.eu.org>), which is maintained by GUTenberg — the French-speaking T  X users group.

C.3.3 Using news groups and forums

*News groups on
T  X and L  T  X*

If precomposed answers are not enough, then there are several news groups and, more importantly, forums that are devoted to general T  X and L  T  X questions. In the past the news groups such as `news://comp.text.tex` have been the premier place to go to and ask questions, but they are now less important for this. If you look at the postings in those groups, most of them are now announcements, intermixed with one or the other thread discussing a question.

*Question and
answer forums on
T  X and L  T  X*

More important therefore are the various forums devoted to T  X and L  T  X: at <https://latex.net/about/> several national and international ones are listed, among them `latex.org` (international), `TeXwelt.de` (German), or `TeXnique.fr` (French). Another recent one is TopAnswers at <https://topanswers.xyz/tex>. Perhaps the most popular one right now is the StackExchange forum on T  X, which you can reach at <https://tex.stackexchange.com>.

In contrast to news groups that also carry announcements and other items of potential short-lived interest, such forums are meant to be a permanent record of problems and their answers. They are therefore usually easy to search and a good place to see if the problem you have has already been raised by others and already has a good answer. So please always search first to avoid asking the same question over and over again, because this wastes everybody else's time. Doing a search engine search normally works well too because the bigger forums such as StackExchange's T  X forum are regularly and often, or even instantly, indexed.

Many of the authors mentioned in this book are regular contributors on forums (or news groups) and help with answering questions and requests. Thus, there is a vast amount of helpful material on the Web that can be conveniently searched using any search engine that indexes news entries.

*How to ask questions
in a smart way*

If you post to any of these news groups or to forums such as StackExchange, please adhere to basic netiquette. The community is friendly but sometimes direct and expects you to have done some research of your own first (e.g., read the FAQ first and search the archived news and questions) and not ask questions that have been answered several hundred times before. You should perhaps read Eric Raymond's "How To Ask Questions The Smart Way", available at <http://www.catb.org/~esr/faqs/smart-questions.html>, as a starter. Also, if applicable, provide a minimal and usable example of your problem (often referred to as an MWE¹) that allows others

¹This stands for "Minimal Working Example", and the stress is on all three words: "Minimal" means you should not just copy a huge file, just because it was the one failing, but condense it so that it contains only what is absolutely needed to show the problem; "Working" means that it should

to easily reproduce the symptoms you experience — this saves others time and might get you a faster and probably more pertinent reply.

Most of the forums allow you to mark an answer as the one that solved your problem. Be courteous and mark it as such if that is the case. It helps others having the same problem, and it always shows that you appreciate the effort somebody else has put into helping you. If there are several useful answers, upvote them all even if you can mark only one as the “correct” solution.

C.3.4 The L^AT_EX Project’s web presence

The L^AT_EX Project Team (i.e., the people who took over from Leslie Lamport, produced L^AT_EX 2_ε, and since then maintained and developed L^AT_EX for you) have an official website that gives pertinent information about L^AT_EX, lists important announcements of upcoming releases and improvements, holds the L^AT_EX newsletters, and hosts a larger collection of the team’s research papers written over the last decades. Keeping a tab on these resources, e.g., by subscribing to the news feed on the page (do not worry, it is low volume, maybe a dozen or so posts per year), helps you to learn about new developments and upcoming features that L^AT_EX is going to offer. You can find the website at <https://latex-project.org> if you have not come across it already.

*Getting news from
the L^AT_EX Project
Team*

The sources for L^AT_EX are hosted on GitHub at <https://github.com/latex3/latex2e> — there releases are built (both the development releases with code for the next major release, as well as the main releases that are done about twice per year). From there they get shipped to CTAN, stored there, and then within a few days make their way into the major T_EX distributions (e.g., T_EX Live or MiK_T_EX), and if you have automatic updates enabled, they appear instantly at your desktop. If not, they appear the next time you update manually.

*The ultimate home
of the L^AT_EX sources*

C.4 Getting all those T_EX files

In contrast to the early days of L^AT_EX, it is nowadays rather easy to get a complete T_EX distribution installed including an update service that fetches missing or changed packages from the Internet and installs them for you. This section therefore only briefly touches on the underlying foundation, the Comprehensive T_EX Archive Network, and the major distributions available.

C.4.1 CTAN — The Comprehensive T_EX Archive Network

The Comprehensive T_EX Archive Network (CTAN for short) is a collaborative effort initiated in 1992 by the T_EX Users Group Technical Working Group on T_EX Archive Guidelines originally coordinated by George Greenwade (1956–2003), building on the earlier work of Peter Abbott (see [60] for the historical background). For a long

compile on its own, e.g., do not expect that the preamble is not important or that it is just enough to show a snippet of the part that is failing; and finally “Example” means it should really be an example of what you are asking about — surprisingly that is not always the case.

time this network of servers for hosting T_EX-related software was maintained by Jim Hefferon, Robin Fairbairns (1947–2022), and Rainer Schöpf. Its services are now offered through a group of volunteers mainly based in Germany. The servers can be reached at the generic address <https://ctan.org> from which you may get redirected to a suitable mirror near to you.

Its main aim is to provide easy access to up-to-date copies of all versions of T_EX, L^AT_EX, METAFONT, and ancillary programs and their associated files. It is the authoritative source of record for most T_EX distributions; i.e., what you get when installing T_EX Live, MiK_T_EX, etc., is a copy of files stored on CTAN and update procedures of such distributions directly or indirectly obtain package updates from there. Thus, most developers submit their packages to CTAN because that is a fast easy and reliable way to get your packages distributed with all major distributions.

However, CTAN also hosts material that for one or the other reason (licensing questions usually) is not automatically part of the distributions, so it is also a place to obtain material that is available but not distributed by default.

All the data hosted on CTAN are cataloged under a larger number of topics, and there are ways to view them by topic or author as well as search them in other ways. That can be helpful if you are looking for packages addressing a certain aspect or supporting a particular language, etc.

The word “Archive” in “Comprehensive T_EX Archive Network” might be a bit misleading: it is an archive in the sense that it archives the latest versions of packages and so holds, for example, also abandoned and obsolete packages only of interest for historical reasons or for reprocessing very old documents, but it is not a historical archive; i.e., you do not find older versions of software on the archive but only the latest release. It does, however, give you a link to the package author repositories if they provided CTAN with that information (where you then usually can find an older release that can be picked up in an emergency).

C.4.2 T_EX distributions — past and present

There are a number of T_EX distributions for installation on laptops and desktops; the most popular ones are probably T_EX Live, MiK_T_EX, and MacT_EX. The T_EX Live distribution is available for different operating systems, which is rather convenient if you are a user of several ones. MiK_T_EX specifically targets Windows operating systems but now also supports Linux. MacT_EX, as the name suggests, is for computers running macOS. All three distributions use software stored on CTAN as their point of reference, either directly or through a curated process repackaging files in the right way for the distribution.

*Enable updates
but also backups!* 

All distributions allow you to receive updates of packages and files, either automatically (if you set it up) or by initiating the update process manually. Staying current with software is often the right thing to do, but be aware that in the case of a major project being worked on (such as your thesis or a book like the one you are reading right now), you may want to stay with a stable version of all software to avoid unpleasant surprises in the last stage of production because of a change altering, say, the pagination. The distributions (except for MiK_T_EX) also allow you to

store backups of updated packages so that it is easy to revert an update if that ever becomes necessary.¹

The T_EX Live distribution has a major update every year since 1996, and from these distribution releases, CDs and later DVDs have been produced and distributed through the T_EX user groups. The original images can be found on the Internet at <https://www.tug.org/texlive/acquire.html#past> from one of the mirrors listed there. They offer you the possibility of reinstalling an older version of the T_EX distribution, if that ever becomes necessary. For very important projects, such as a book production or a thesis, it may pay off to keep an image from that time next to it to have some level of assurance that you have everything available that was used at the time to reproduce the work. Of course, this gives you only the single snapshot of the distribution at a particular point in time (including the binaries). Given that throughout a year packages typically get updated, you should additionally look at the tools discussed in Section 2.5.2 on page 110 to get the full set of files you used in your project.

Keep images of the distribution if possible

Linux distributions

Most flavors of Linux contain T_EX distributions that can be installed through the package manager of the Linux distribution you use. For a number of reasons these distributions may not use the most current T_EX Live release, and if you use them to install a T_EX distribution, you obtain something that is sometimes years behind a current distribution. For that reason our advice is to forget these native Linux packages, but instead take a current T_EX Live distribution and use that for installation on your system. The installation is fairly straightforward, and if you know how to work the package manager of your Linux system, then following the installation procedures for T_EX Live should pose no difficulties — your reward will be a current and up-to-date T_EX installation.

 *Avoid pre-made Linux packages for T_EX — or at least check that they contain a recent release*

Cloud service installations

In the recent years cloud services such as Overleaf have become popular. They make L^AT_EX available as online installations that allow for easy collaboration between several people, because the documents are stored and processed in the cloud. This also means that everybody is using the same packages on identical release levels (i.e., no issue with one of your colleagues using a different L^AT_EX release than the others), nobody is forced to install a distribution on their computer before starting to collaborate, and you have or can have version control of your documents, and several other goodies. There are, of course, also some downsides, e.g., you are restricted in your editing environment because (by default) you are working in the browser, you may not be able to use cutting-edge package versions, etc., but on the whole they offer a great environment for collaborating and significantly lower the entry barrier to using L^AT_EX.

Under the hood, a service such as the one from Overleaf uses T_EX Live distributions, so all that is described in this book is fully applicable without restriction. This

¹This is seldom needed, but it provides you with a valuable safety net if some update affects your workflow in some unexpected way. Note that this is not offered by MiK_T_EX.

also goes for the advice given above that it is useful to keep a copy of the relevant distribution files as a DVD image together with important documentation projects because that significantly enlarges the chances that your files remain fully processable even after many years.

A simple cloud service without registration

A simpler online service, <https://texlive.net>, has been developed by David Carlisle as part of the Learn \LaTeX project discussed in Appendix C.1. It gives online access to a \TeX Live installation without requiring any login or registration and integrates an online editor. However, it provides no mechanism to save documents, so is suitable only for small examples. By default it uses \LaTeX with the `pdftex` engine, but the engine may be changed via a comment line such as

```
% !TeX lualatex
```

at the top of the document.

C.5 Giving back to the community

Open source software lives from the volunteers who engage in its development and maintenance. In the early days of \TeX , many people using \TeX directly engaged with the developer community or became part of it because using \TeX and \LaTeX meant that you had to work through many obstacles, starting from installation (which was a largely manual step) to finding packages (that were not well organized in one place or automatically showed up at your doorstep by just installing a pre-canned distribution) down to developing your own packages because your problem was not yet solved.

Over time more and more of this got streamlined, installations became simple due to distributions such as \TeX Live [191], central repositories appeared and are well maintained, i.e., CTAN, and over the last decades more and more ready-to-use packages for all kind of tasks were developed — the growing size of this book from edition to edition is a living proof of that.

As a result, the continuing work of volunteers in the background to make this all happen smoothly faded more and more from people's minds, and many users now have no idea that nothing would work if there were not a handful of people spending their free time curating several dozen package updates per day, building new distributions regularly, or maintaining and developing \LaTeX and the many packages out there, etc.

Everything just seems to work and is at your fingertips, whether you are producing your documents on an online platform such as Overleaf or whether you download an installation for your local machine from the Internet. However, it is not quite as simple as that. Developers need resources to successfully do their work, they need a lively community through which they can exchange ideas and get feedback on work being undertaken, and they need appreciation of their work by their users.

There are many ways in which you can help to keep that ship afloat, starting from showing your appreciation after asking for help and receiving it to more substantial ways, such as contributing to one or the other project. All of them are necessary and helpful, and this final short section shows some ways through which you can make a difference.

In the *T_EXbook* [84, app. J] Donald Knuth wrote an appendix called “Joining the T_EX Community”, which is still as relevant as it was forty years ago. Only back then, the benefits of joining a user group and paying a membership fee was obvious to many (because it was the best if not the only way to get in contact with other users and receive help), while today only a few people compared to the user base even know about such groups, let alone think that the user groups offer them any immediate benefit. Immediate — perhaps not, but in the long term most certainly yes for the reasons outlined above, so please consider becoming officially a part of the community and supporting the mission.

There is the international T_EX Users Group (TUG) that publishes a regular journal and organizes conferences at which developers and users meet and interact. You can reach TUG at <https://tug.org>. Membership fees and/or donations to TUG or specific projects are tax-deductible in the United States. There are also several local user groups around the world, mostly based on language affinities, that are doing similar work; a current inventory is provided at <https://tug.org/lugs.html> to help you find one in your local language, but note that some are more active than others.

There is also the possibility of donating to specific projects that are of interest to you or whose work you want to specifically support either through TUG at <https://tug.org/donate> or by supporting individual developers. GitHub, for example, offers a way to sponsor developers with a recurring (smaller or larger) contribution, and besides paying for the coffee or other essentials needed to do night-long work on maintaining or developing software, this is a way of showing appreciation that is valued far higher by most than the actual monetary value.

Bibliography

- [1] Adobe Systems Incorporated. Adobe Type 1 Font Format. Addison-Wesley, Reading, MA, USA, 1990. ISBN 0-201-57044-0.
The “black” book contains the specifications for Adobe’s Type 1 font format and describes how to create a Type 1 font program. It explains the specifics of the Type 1 syntax (a subset of PostScript), including information on the structure of font programs, ways to specify computer outlines, and the contents of the various font dictionaries. It also covers encryption, subroutines, and hints. https://adobe-type-tools.github.io/font-tech-notes/pdfs/T1_SPEC.pdf
- [2] American Mathematical Society. User’s Guide to AMSFonts Version 2.2d. Providence, Rhode Island, 2002.
This document describes AMSFonts, the American Mathematical Society’s collection of fonts of symbols and several alphabets. <https://www.ctan.org/pkg/amsfonts>
- [3] ———. Using the amsthm Package (Version 2.20.3). Providence, Rhode Island, 2017.
The amsthm package provides an enhanced version of \LaTeX ’s `\newtheorem` command for defining theorem-like environments, recognizing `\theoremstyle` specifications and providing a `proof` environment. <https://www.ams.org/arc/tex/amscls/amsthdoc.pdf>
- [4] ———. AMS Author Handbook (website). Providence, Rhode Island, 2021.
Entry point to documentation and support packages for preparing articles and books for publication with the American Mathematical Society. <https://www.ams.org/arc/handbook/index.html>
- [5] American Mathematical Society and \LaTeX Project. User’s Guide for the `amsmath` Package (Version 2.1), 2020.
The `amsmath` package, developed by the American Mathematical Society, provides many additional features for mathematical typesetting. It is now maintained by the \LaTeX Project team.
Locally available via: `texdoc amsmath`
- [6] American Psychological Association. Publication Manual of the American Psychological Association. APA, 7th edition, 2020.
The official style guide of the American Psychological Association (APA) for the preparation of manuscripts for publication, as well as for writing student papers, dissertations, and theses. <https://apastyle.apa.org/>

- [7] Anonymous. “‘thanks’ note (footnote) placed below right column even though there is enough space on the left”. *StackExchange*, 2012.
An example of a question on a strange footnote placement by L^AT_EX. The answers explains some of the reasons why this can happen. <https://tex.stackexchange.com/questions/43294>
- [8] Apple Inc. “TrueType Reference Manual”, 2019.
Apple’s reference manual for the TrueType font format.
<https://developer.apple.com/fonts/TrueType-Reference-Manual>
- [9] Donald Arseneau. *url.sty—Version 3.4*, 2016.
Documentation provided by Robin Fairbairns (1947–2022). Locally available via: `texdoc url`
- [10] Michael Barr. A new diagram package, 2016.
A rewrite of Michael Barr’s original *diagram* package to act as a front end to Rose’s *xypic*; see [55, Chapter 7]. It offers a general arrow-drawing function; various common diagram shapes, such as squares, triangles, cubes, and 3×3 diagrams; small 2-arrows that can be placed anywhere in a diagram; and access to all of *xypic*’s features. Locally available via: `texdoc diagxy`
- [11] Claudio Beccari and Apostolos Syropoulos. “New Greek fonts and the greek option of the babel package”. *TUGboat*, 19(4):419–425, 1998.
Describes a new complete set of Greek fonts and their use in connection with babel’s greek extension.
<https://tug.org/TUGboat/tb19-4/tb61becc.pdf>
- [12] Nelson Beebe. “Bibliography prettyprinting and syntax checking”. *TUGboat*, 14(4):395–419, 1993.
This article describes three software tools for B^WT_EX support: a prettyprinter, syntax checker, and lexical analyzer for B^WT_EX files; collectively called *bibclean*.
<https://tug.org/TUGboat/tb14-4/tb41beebe.pdf>
- [13] Barbara Beeton. “Mathematical symbols and Cyrillic fonts ready for distribution”. *TUGboat*, 6(2):59–63, 1985.
The announcement of the first general release by the American Mathematical Society of the Euler series fonts.
<https://tug.org/TUGboat/tb06-2/tb11beet.pdf>
- [14] Alexander Berdnikov, Olga Lapko, Mikhail Kolodin, Andrew Janishevsky, and Alexei Burykin. “Cyrillic encodings for L^AT_EX 2_ε multi-language documents”. *TUGboat*, 19(4):403–416, 1998.
A description of four encodings designed to support Cyrillic writing systems for the multi-language mode of L^AT_EX 2_ε. The “raw” X2 encoding is a Cyrillic glyph container that allows one to insert into L^AT_EX 2_ε documents text fragments written in any of the languages using a modern Cyrillic writing scheme. The T2A, T2B, and T2C encodings are genuine L^AT_EX 2_ε encodings that may be used in a multi-language setting together with other language encodings.
<https://tug.org/TUGboat/tb19-4/tb61berd.pdf>
- [15] Jens Berger. “The jurabib Package”, 2017.
Manual for the jurabib package, translated to English by Maarten Wisse.
Locally available via: `texdoc jurabib`
- [16] Karl Berry. “Filenames for fonts”. *TUGboat*, 11(4):517–520, 1990.
This article describes the consistent, rational scheme for font file names that was used for at least the next 15 years. Each name consists of up to eight characters (specifying the foundry, typeface name, weight, variant, expansion characteristics, and design size) that identify each font file in a unique way.
<https://tug.org/TUGboat/tb11-4/tb30berry.pdf>
The latest version of this scheme is available at: <https://tug.org/fontname/html/>

- [24] Peter Breitenlohner et al. “The $\text{eT}_{\text{E}}\text{X}$ manual (version 2)”, 1998.
The current manual for the $\text{eT}_{\text{E}}\text{X}$ system, which extends the capabilities of $\text{T}_{\text{E}}\text{X}$ while retaining compatibility. While the $\text{eT}_{\text{E}}\text{X}$ engine is considered obsolete these days, its extensions have been implemented in all major modern systems and $\text{L}_{\text{A}}\text{T}_{\text{E}}\text{X}$ expects them to be available. Thus, the documentation remains relevant. [Locally available via: `texdoc etex`](#)
- [25] Robert Bringhurst. The elements of typographic style (20th Anniversary edition). Hartley & Marks Publishers, Point Roberts, WA, USA, and Vancouver, BC, Canada, 4th edition, 2013. ISBN 0-88179-212-8 (hardcover).
A very well-written book on typography with a focus on the proper use of typefaces.
- [26] ———. Palatino — The Natural History of a Typeface. David R. Godine, Publisher, Boston, 2016. ISBN 978-1-56792-572-2.
Palatino is one of the most widely used typefaces today. Designed by Hermann Zapf (1918–2015), it has been used as a model for many other typefaces. This book discusses its evolution and history and is a fascinating read if you are interested in type design.
- [27] Bureau International des Poids et Mesures. SI Brochure: The International System of Units (SI), 9th edition, 2019.
The 9th edition of the brochure explaining and promoting the International System of Units (SI) — the preferred system of units for science, technology, industry and trade. Available in English and French.
<https://www.bipm.org/en/publications/si-brochure/>

- [28] Judith Butcher, Caroline Drake, and Maureen Leach. *Butcher's Copy-editing: The Cambridge Handbook for Editors, Copy-editors and Proofreaders*. Cambridge University Press, New York, forth edition, 2006. ISBN 0-521-40074-0.
A reference guide for all those involved in the process of preparing typescripts and illustrations for printing and publication. The book covers all aspects of the editorial process, from the basics of how to mark a typescript for the designer and the typesetter, through the ground rules of house style and consistency, to how to read and correct proofs.
- [29] Florian Cajori. *A History of Mathematical Notations*. Dover Publications, New York, 1993. ISBN 978-0-486-67766-8.
This classic book on mathematical notations, originally published in two volumes in 1928-1929, devotes a full chapter to several numeral systems from antiquity, including Greek.
- [30] David Carlisle. "A \LaTeX tour, Part 1: The basic distribution". *TUGboat*, 17(1):67-73, 1996.
A "guided tour" around the files in the basic \LaTeX distribution. File names and paths relate to the file hierarchy of the CTAN archives. <https://tug.org/TUGboat/tb17-1/tb50carl.pdf>
- [31] ———. "A \LaTeX tour, Part 2: The tools and graphics distributions". *TUGboat*, 17(3):321-326, 1996.
A "guided tour" around the "tools" and "graphics" packages. Note that *The Manual* [106] assumes that at least the graphics distribution is available with standard \LaTeX .
<https://tug.org/TUGboat/tb17-3/tb52carl.pdf>
- [32] ———. "A \LaTeX tour, Part 3: mfnfss, psnfss and babel". *TUGboat*, 18(1):48-55, 1997.
A "guided tour" through three more distributions that are part of the standard \LaTeX system. The mfnfss distribution provides \LaTeX support for some popular METAFONT-produced fonts that do not otherwise have any \LaTeX interface. The psnfss distribution consists of \LaTeX packages giving access to PostScript fonts. The babel distribution provides \LaTeX with multilingual capabilities.
<https://tug.org/TUGboat/tb18-1/tb54carl.pdf>
- [33] ———. "XMLTEX: A non validating (and not 100% conforming) namespace aware XML parser implemented in \TeX ". *TUGboat*, 21(3):193-199, 2000.
XMLTEX is an XML parser and typesetter implemented in \TeX , which by default uses the \LaTeX kernel to provide typesetting functionality. <https://tug.org/TUGboat/tb21-3/tb68carl.pdf>
- [34] David Carlisle, editor. *Mathematical Markup Language (MathML) Version 4.0*. W3C, 1st edition, 2023.
This is the draft specification for a new version of the Mathematical Markup Language; the current version is 3.0 [35]. MathML4 extensions primarily relate to improving accessibility, with new attributes for improving audio rendering. <https://www.w3.org/TR/mathml4/>
- [35] David Carlisle, Patrick Ion, and Robert Miner, editors. *Mathematical Markup Language (MathML) Version 3.0*. W3C, 2nd edition, 2014.
This is the current specification defining the Mathematical Markup Language; the upcoming version will be [34]. MathML is an XML vocabulary for mathematics, designed for use in browsers and as a communication language between computer algebra systems. The goal of MathML is to enable mathematics to be served, received, and processed on the World Wide Web, just as HTML has enabled this functionality for text. <https://www.w3.org/TR/MathML3/>
- [36] David Carlisle, Patrick Ion, Robert Miner, and Nico Poppelier, editors. *Mathematical Markup Language (MathML) Version 2.0*. W3C, 2nd edition, 2003.
This is the previous version of the MathML standard [35]. <https://www.w3.org/TR/MathML2/>

- [37] David Carlisle, Chris Rowley, and Frank Mittelbach. “The \LaTeX 3 Programming Language—a proposed system for \TeX macro programming”. *TUGboat*, 18(4):303–308, 1997.
Initial proposals for a radically new syntax and software tools. Most of them are now part of the \LaTeX format as the L3 programming layer. <https://tug.org/TUGboat/tb18-4/tb57row1.pdf>
- [38] Jean Pierre Casteleyn. *Visual TikZ*, 2019.
A great resource with hundreds of examples, structured by topic, enabling you to find and apply necessary key combinations rather easily. [Locally available via: `texdoc visualtikz`](#)

- [40] The Chicago Manual of Style. University of Chicago Press, Chicago, IL, USA, 17th edition, 2017. ISBN 978-0-226-28705-8.
The standard U.S. publishing style reference for authors and editors. <https://www.chicagomanualofstyle.org>
- [41] Comprehensive \TeX archive network (CTAN). “Topic page on tikz”.
Links to CTAN’s resources for the tikz universe. <https://www.ctan.org/topic/pgf-tikz>
- [42] Carl Dair. *Design with Type*. University of Toronto Press, Toronto, Ontario, Canada, 1967. ISBN 0-8020-1426-7 (hardcover), 0-8020-6519-8 (paperback).
Published in the year of Dair’s death, this book is a classic and a good survey of traditional typography with many useful rules of thumb. There was a reprint in 1982, which is still available.
- [43] Ioannis Dimakos and Dimitrios Filippou. “Twenty-five years of Greek \TeX ing”. *Eutypou*, 32–33:25–34, 2014.
An overview about available tools (fonts, systems, etc.) for typesetting Greek texts with \TeX / \LaTeX . <https://ctan.org/tex-archive/info/greek/greekinfo3>
- [44] Michael Downes. “Breaking equations”. *TUGboat*, 18(3):182–194, 1997.
 \TeX is not very good at displaying equations that must be broken into multiple lines. The `breqn` package eliminates many of the most significant problems by supporting automatic line breaking of displayed equations. <https://tug.org/TUGboat/tb18-3/tb56down.pdf>
- [45] ———. “The `amsrefs` \LaTeX package and the `amsxport` Bib \TeX style”. *TUGboat*, 21(3):201–209, 2000.
Bibliography entries using the `amsrefs` format provide a rich internal structure and high-level markup close to that traditionally found in Bib \TeX database files. On top of that, using `amsrefs` markup lets you specify the bibliography style completely in a \LaTeX document class file. <https://tug.org/TUGboat/tb21-3/tb68down.pdf>
- [46] Michael Downes, Høgholm, and Will Robertson. *The breqn package*, 2021.
A package initially developed by Michael Downes (1958–2003) for automatically breaking display equations into several lines [44]. Continued after Michael’s death by Morten Høgholm and Will Robertson. [Locally available via: `texdoc breqn`](#)
- [47] Olaf Drümmer and Bettina Chang. *PDF/UA in a Nutshell — Accessible documents with Portable Document Format (PDF)*. PDF Association, 2013.
A nice introduction to the ISO standard 14289-1 for universal accessibility, also known as PDF/UA [190]. It provides key facts, e.g., the requirements of the standard, the current legal situation, etc. <https://pdfa.org/resource/pdfua-in-a-nutshell/>

- [48] Dudenredaktion, editor. Die deutsche Rechtschreibung. Dudenverlag, Berlin, 28th edition, 2020. ISBN 978-3-411-04018-6.
The standard reference for the correct spelling of all words of contemporary German and for hyphenation rules, with examples and explanations for difficult cases, and a comparison of the old and new orthographic rules.
- [49] Victor Eijkhout. *T_EX by Topic, A T_EXnician's Reference*. Lehmanns Media, Berlin, 2014. ISBN 978-3-86541-590-5. Reprint with corrections. Initially published in 1991 by Addison-Wesley. Also available free of charge from the author in PDF format.
A systematic reference manual for the experienced T_EX user. The book offers a comprehensive treatment of every aspect of T_EX (not L^AT_EX!), with detailed explanations of the mechanisms underlying T_EX's working, as well as numerous examples of T_EX programming techniques.
<https://eijkhout.net/tex/tex-by-topic.html>
- [50] FUJITA Shinsaku and NOBUYA Tanaka. “X_YM_TE_X (Version 2.00) as implementation of the X_YM notation and the X_YM markup language”. *TUGboat*, 21(1):7–14, 2000.
A description of version 2 of the X_YM_TE_X system, which can be regarded as a linear notation system expressed in T_EX macros that corresponds to the IUPAC (International Union of Pure and Applied Chemistry) nomenclature. It provides a convenient method for drawing complicated structural formulas.
<http://tug.org/TUGboat/tb21-1/tb66fuji.pdf>
- [51] ———. “Size reduction of chemical structural formulas in X_YM_TE_X (Version 3.00)”. *TUGboat*, 22(4):285–289, 2001.
Further improvements to the X_YM_TE_X system, in particular in the area of size reduction of structural formulas.
<https://tug.org/TUGboat/tb22-4/tb72fuji.pdf>
- [52] FUKUI Rei. “TIPA: A system for processing phonetic symbols in L^AT_EX”. *TUGboat*, 17(2):102–114, 1996.
TIPA is a system for processing symbols of the International Phonetic Alphabet with L^AT_EX. It introduces a new encoding for phonetic symbols (T3), which includes all the symbols and diacritics found in the recent versions of IPA as well as some non-IPA symbols. It has full support for L^AT_EX 2_ε and offers an easy input method in the IPA environment.
<https://tug.org/TUGboat/tb17-2/tb51rei.pdf>
- [53] Maarten Gelderman. “A short introduction to font characteristics”. *TUGboat*, 20(2):96–104, 1999.
This paper provides a description of the main aspects used to describe a font, its basic characteristics, elementary numerical dimensions to access properties of a typeface design, and the notion of “contrast”.
<https://tug.org/TUGboat/tb20-2/tb63geld.pdf>
- [54] Norbert Golluch. *Kleinweich Büro auf Schlabberscheiben — Technisches Deutsch für Anfänger*. Eichborn, Frankfurt, 1999.
As the title indicates, a booklet with funny but incorrect translations of IT terms to German.
- [55] Michel Goossens, Frank Mittelbach, Sebastian Rahtz, Denis Roegel, and Herbert Voß. *The L^AT_EX Graphics Companion*. Lehmanns Media, Köln, 2nd edition, 2022. ISBN 978-3-96543-303-8 (softcover), 978-3-96543-299-4 (ebook).
Reprint of the 2nd edition originally published by Addison-Wesley in the Tools and Techniques for Computer Typesetting series.
The book describes all aspects of generating and manipulating graphical material in L^AT_EX, including an in-depth coverage of pstricks, METAFONT and METAPOST, xcolor, xy, etc., as well as a thorough overview about applications in science, technology, medicine, gaming, and musical notation.

- [56] Michel Goossens, Frank Mittelbach, and Alexander Samarin. *The L^AT_EX Companion. Tools and Techniques for Computer Typesetting*. Addison-Wesley, Reading, MA, USA, 1994. ISBN 0-201-54199-8.
The first edition of this book. The second edition [145] was published ten years later in 2004.
- [57] Michel Goossens and Sebastian Rahtz. *The L^AT_EX Web Companion: Integrating T_EX, HTML, and XML. Tools and Techniques for Computer Typesetting*. Addison-Wesley, Reading, MA, USA, 1999. ISBN 0-201-43311-7. With Eitan M. Gurari, Ross Moore, and Robert S. Sutor.
This book teaches (scientific) authors how to publish on the Web or other hypertext presentation systems, building on their experience with L^AT_EX and taking into account their specific needs in fields such as mathematics, non-European languages, and algorithmic graphics. The book explains how to make full use of the Adobe Acrobat format from L^AT_EX, convert legacy documents to HTML or XML, make use of math in Web applications, use L^AT_EX as a tool in preparing Web pages, read and write simple XML/SGML, and produce high-quality printed pages from Web-hosted XML or HTML pages using T_EX or PDF.
- [58] Ronald L. Graham, Donald E. Knuth, and Oren Patashnik. *Concrete Mathematics*. Addison-Wesley, Reading, MA, USA, 2nd edition, 1994. ISBN 0-201-55802-5.
A mathematics textbook prepared with T_EX using the Concrete Roman typeface; see also [94].
- [59] George Grätzer. *More Math Into LaTeX*. Springer International Publishing, Cham, Switzerland, 5th edition, 2016. ISBN 3-319-23795-0.
Provides a general introduction to L^AT_EX as used to prepare mathematical books and articles. Covers AMS document classes and packages in addition to the basic L^AT_EX offerings.
- [60] George D. Greenwade. “The Comprehensive T_EX Archive Network (CTAN)”. *TUGboat*, 14(3):342–351, 1993.
An outline of the conception, development, and early use of the CTAN archive, which makes all T_EX-related files available on the network. <https://tug.org/TUGboat/tb14-3/tb40green.pdf>
- [61] Hàn Thế Thành. “Improving T_EX’s typeset layout”. *TUGboat*, 19(3):284–288, 1998.
This attempt to improve T_EX’s typeset layout is based on the adjustment of interword spacing after the paragraphs have been broken into lines. Instead of changing only the interword spacing to justify text lines, fonts on the line are also slightly expanded to minimize excessive stretching of the interword spaces. This font expansion is implemented using horizontal scaling in PDF. By using such expansion conservatively, and by employing appropriate settings for T_EX’s line-breaking and spacing parameters, this method can improve the appearance of T_EX’s typeset layout. <https://tug.org/TUGboat/tb19-3/tb60than.pdf>
- [62] ———. “Micro-typographic extensions to the T_EX typesetting system”. *TUGboat*, 21(4):317–434, 2000.
Doctoral dissertation at the Faculty of Informatics, Masaryk University, Brno, Czech Republic, October 2000. <https://tug.org/TUGboat/tb21-4/tb69thanh.pdf>
- [63] ———. “Margin kerning and font expansion with pdfT_EX”. *TUGboat*, 22(3):146–148, 2001.
“Margin kerning” adjusts the positions of the primary and final glyphs in a line of text to make the margins “look straight”. “Font expansion” uses a slightly wider or narrower variant of a font to make interword spacing more even. These techniques are explained with the help of examples. For a detailed explanation of the concepts, see [62]. This feature was used in the preparation of this book. <https://tug.org/TUGboat/tb22-3/tb72thanh.pdf>

- [64] ———. “Font-specific issues in pdfTeX”. *TUGboat*, 29(1):36–41, 2008.
Overview article on font-specific problems and (possible) solutions. In parts related to challenges posed in [128]. <http://www.tug.org/TUGboat/tb29-1/tb91thanh-fonts.pdf>
- [65] Hàn Thế Thành and Sebastian Rahtz. “The pdfTeX user manual”. *TUGboat*, 18(4):249–254, 1997.
User manual for the pdfTeX system, which extends TeX to generate PDF directly and provides various micro-typographic extensions; see [61–64].

- [84] ———. The \TeX book, volume A of *Computers and Typesetting*. Addison-Wesley, Reading, MA, USA, 1986. ISBN 0-201-13447-0. Jubilee 2021 edition, twenty-fifth printing with corrections.
The definitive user's guide and complete reference manual for \TeX . A good secondary reading, covering the same grounds, is [49].
- [85] ———. \TeX : The Program, volume B of *Computers and Typesetting*. Addison-Wesley, Reading, MA, USA, 1986. ISBN 0-201-13437-3. Jubilee 2021 edition, thirteenth printing with corrections.
The complete source code for the \TeX program, typeset with several indices.
- [86] ———. The METAFONTbook, volume C of *Computers and Typesetting*. Addison-Wesley, Reading, MA, USA, 1986. ISBN 0-201-13445-4 (hardcover), 0-201-13444-6 (paperback). Jubilee 2021 edition, twelfth printing with corrections.
The user's guide and reference manual for METAFONT, the companion program to \TeX for designing fonts.
- [87] ———. METAFONT: The Program, volume D of *Computers and Typesetting*. Addison-Wesley, Reading, MA, USA, 1986. ISBN 0-201-13438-1. Jubilee 2021 edition, eleventh printing with corrections.
The complete source code listing of the METAFONT program.
- [88] ———. Computer Modern Typefaces, volume E of *Computers and Typesetting*. Addison-Wesley, Reading, MA, USA, 1986. ISBN 0-201-13446-2. Jubilee 2021 edition, eleventh printing with corrections.
More than 500 Greek and Roman letterforms, together with punctuation marks, numerals, and many mathematical symbols, are graphically depicted. The METAFONT code to generate each glyph is given and it is explained how, by changing the parameters in the METAFONT code, all characters in the Computer Modern family of typefaces can be obtained.
- [89] ———. 3:16 Bible texts illuminated. A-R Editions, Inc., Madison, Wisconsin, 1990. ISBN 0-89579-252-4.
Analysis of Chapter 3 Verse 16 of each book of the Bible. Contains wonderful calligraphy by various artists.
- [90] ———. The Art of Computer Programming, volumes 1–4A and Fascicles 5–6. Addison-Wesley, Reading, MA, USA, 1998–2019. ISBN 0-201-89683-4, 0-201-03822-6, 0-201-03803-X, 0-201-03804-8, 0-13-467179-1, and 0-13-439760-6.
Donald Knuth's major work on algorithms and data structures for efficient programming.
- [91] ———. Digital Typography. CSLI Publications, Stanford, CA, USA, 1999. ISBN 1-57586-011-2 (cloth), 1-57586-010-4 (paperback).
A comprehensive collection of Knuth's writings on \TeX and typography. While many articles in this collection are available separately on the Web, not all of them are, and having them all in one place for studying is an additional benefit.
- [92] ———. "Mathematical typography". In Knuth [91], pp. 19–65.
Based on a lecture he gave in 1978, Knuth makes the point that mathematics books and journals do not look as beautiful now as they did in the past. Because this is mainly due to the fact that high-quality typesetting has become too expensive, he proposes to use mathematics itself to solve the problem. As a first step he sees the development of a method to unambiguously mark up the math elements in a document so that they can be easily handled by machines. The second step is to use mathematics to design the shapes of letters and symbols. The article goes into the details of these two approaches.

- [93] ———. “Virtual fonts: More fun for grand wizards”. In Knuth [91], pp. 247–262.
An explanation of what virtual fonts are and why they are needed, plus technical details.
Originally published as: <https://tug.org/TUGboat/tb11-1/tb27knut.pdf>
- [94] ———. “Typesetting Concrete Mathematics”. In Knuth [91], pp. 367–378.
Knuth explains how he prepared the textbook *Concrete Mathematics*. He states that he wanted to make that book both mathematically and typographically “interesting”, since it would be the first major use of Herman Zapf’s new typeface, AMS Euler. The font parameters were tuned up to make the text look as good as that produced by the best handwriting of a mathematician. Other design decisions for the book are also described.

- [98] ———. “A footnote about ‘Oh, oh, zero’”. *TUGboat*, 35(3):232–234, 2014.
Notes on early typesetting of computer programs by the ACM and Addison-Wesley as an addendum to [20] resulting in the development of a DK version of the Lucida monospaced fonts [21].
<https://tug.org/TUGboat/tb35-3/tb111knut-zero.pdf>
- [99] Donald E. Knuth and Michael F. Plass. “Breaking paragraphs into lines”. In Knuth [91], pp. 67–155.
This article, originally published in 1981, addresses the problem of dividing the text of a paragraph into lines of approximately equal length. The basic algorithm considers the paragraph as a whole and introduces the (now well-known T_EX) concepts of “boxes”, “glue”, and “penalties” to find optimal breakpoints for the lines. The paper describes the dynamic programming technique used to implement the algorithm.
- [100] Donald E. Knuth and Hermann Zapf. “AMS Euler—A new typeface for mathematics”. In Knuth [91], pp. 339–366. Originally published in *Scholarly Publishing* 20 (1989), 131–157.
The two authors explain, in this article originally published in 1989, how a collaboration between scientists and artists is helping to bring beauty to the pages of mathematical journals and textbooks.

- [135] ———. “Effective floating strategies”. In “Proceedings of the 2017 ACM Symposium on Document Engineering”, DocEng’17, pp. 29–38. Association for Computing Machinery, New York, NY, USA, 2017. ISBN 978-1-4503-4689-4.

This paper presents an extension to the general framework for globally optimized pagination described [134]. The extended algorithm supports automatic placement of floats as part of the optimization using a flexible constraint model that allows for the implementation of typical typographic rules.

- [140] Frank Mittelbach, David Carlisle, and Chris Rowley. “Experimental L^AT_EX code for class design”. Vancouver, 1999.

At the T_EX Users Group conference in Vancouver the L^AT_EX project team gave a talk on models for user-level interfaces and designer-level interfaces in L^AT_EX3 [141]. Most of these ideas have been implemented in prototype implementations (e.g., template design, front matter handling, output routine, galley and paragraph formatting). The source code is documented and contains further explanations and examples; see also [131]. The underlying programming interfaces are since 2020 part of the L^AT_EX format as the L3 programming layer [115].

- [194] Gabriel Valiente Feruglio. “Modern Catalan typographical conventions”. *TUGboat*, 16(3):329–338, 1995.
Many languages, such as German, English, and French, have a long established typography tradition. However, despite the existence of a well-established tradition in scientific writing in Catalan, there are not yet any standards encompassing typographical conventions in this area. This paper proposes typographical rules that reflect the spirit of ancient Catalan scientific writings while conforming to modern typographical conventions. Some of these typographical rules are incorporated in Catalan extensions to T_EX and L^AT_EX. The proposal also hopes to contribute to the development of standard rules for scientific writing in Catalan.

Index of Commands and Concepts

This title somewhat hides the fact that everything (for both volumes) except for names of people is in this one long comprehensive index. To make it easier to use, the entries are distinguished by their “type”, and this is often indicated by one of the following “type words” at the beginning of the main entry or a subentry:

attribute, BibTeX/biber command, BibTeX entry type, BibTeX field, BibTeX style, boolean, counter, document class, env., file, file extension, folio style, font encoding, hook, key/option, keyword, key, language, length, library, math accent, math symbol, option, package, page style, program, rigid length, syntax, text accent, text symbol, text/math symbol, TeX counter, or value.

Most “type words” should be fairly self-explanatory, but a few need some explanation to help you find the entries you are looking for.

‘option’ and ‘keyoption’ Both type words indicate that the keyword can be used in the optional argument of `\usepackage`. If the option accepts a value, it is marked as a ‘keyoption’ and otherwise as a classic ‘option’. Most packages with ‘keyoptions’ also offer configuration commands that can be used in the preamble or in the document body — see also next types.

‘key’ and ‘value’ Many modern L^AT_EX packages implement a key/value syntax (i.e., $\langle key_1 \rangle = \langle value_1 \rangle, \langle key_2 \rangle = \langle value \rangle, \dots$) as part of the optional argument to `\usepackage`, in arguments of commands or environments, or both. Keywords that can appear to the left of the equal sign are indicated by the type word ‘key’ (or as type ‘keyoption’ if allowed in `\usepackage`), those that can appear to the right

as ‘value’. Sometimes keywords can appear on either side, depending on context, in which case they are indexed according to their use on the particular page.¹

‘syntax’ Keywords and strings marked with ‘syntax’ can appear in arguments of commands but are not part of a key/value pair.

‘counter’ and ‘TeX counter’ Names marked as ‘counter’ are TeX counters and are altered with `\setcounter`, etc., while ‘TeX counters’ start with a backslash and use a low-level method for modification.

‘length’ and ‘rigid length’ A ‘length’ register can take values with a plus and minus component, i.e., can stretch or shrink. In contrast, a ‘rigid length’ stores only a fixed value. Most lengths in TeX are flexible, i.e., not rigid.

‘text symbol’, ‘math symbol’, and ‘text/math symbol’ A command is classified as a ‘text symbol’ if it typesets a glyph for use in text, whereas a ‘math symbol’ can be used only in math mode and produces an error elsewhere. A few symbols are allowed everywhere and are therefore of type ‘text/math symbol’.

In most cases, the actual symbol is also shown in the index entry to help you find the symbol you are looking for more easily (the command names are not always obvious). Note, however, that the glyph shown is only an approximation of reality—in your document it may come out differently depending on the fonts you use.

no type word indication The absence of an explicit “type word” means that the “type” is either a core TeX command or simply a concept.

If a particular index entry is defined or used in a special way by a package, then this is indicated by adding the package name (in parentheses) to an entry or subentry. If package `aaa` builds upon or extends package `bbb`, we indicate this with `(aaa/bbb)`. There is one “virtual” package name, `tlc`, which indicates commands introduced only for illustrative purposes in this book. Again, you may see `(tlc/bbb)`, if appropriate.

The index contains all entries for both volumes. To which pages the references point is indicated by `→I` (for part one) and `→II` (for part two). To save space, these indicators are given only once in each entry. An *italic* page number indicates that the command or concept is demonstrated in an example on that page. When there are several page numbers listed, **blue boldface** indicates a page containing important information about an entry, such as a definition or basic usage. However, **bold** is (normally) not used for concept entries, when all entries are of equal importance, or when there is *only one* page reference.

When looking for the position of an entry in the index, you need to realize that both of the characters `\` and `.` are ignored when they come at the start of a command or file extension. Other syntax entries starting with a period are listed in the Symbols section. Otherwise, the index entries are sorted in ASCII order, and the running header gives you an indication where you are in the index. For the rather lengthy Symbols section at the beginning of the index, this is unfortunately of little help because only a few people would know the symbol order in the ASCII encoding. We therefore show the order of symbols in the margin on those pages.

¹This explains why you might find the same keyword under both type words, but given that one is usually interested only in one type of usage, this distinction is made. This distinction also exhibits the fact that different packages use the same keywords in different ways—an unfortunate side effect of the long history of TeX package development by independent developers.

\PackageNoteNoLine, →II 706

packages, *see also* development tools, l3build

combining in one file, →I 109f.

commands, →II 628, 694, 704–708

definition, →I 22

descriptions, online catalogue, →II 787, 790

documentation, finding, →II 786f.

documenting, *see* documentation tools

file structure, →II 693–708

in this book, →II 977–982

local, distributing, →I 109f.

modifying, →I 25

multiple, with same option settings, →I 25

processing, →I 24, 25f.

search paths, →II 785f.

using earlier versions, →I 114–118, →II 693ff.

a4 *obsolete*, →I 374, *see instead* geometry package

a4dutch *obsolete*, →I 374, *see instead* geometry

a4wide *obsolete*, →I 374, *see instead* geometry

a5 *obsolete*, →I 374, *see instead* geometry

a5comb *obsolete*, →I 374, *see instead* geometry

abraces, →II 185–189

abstract, →I 28

accanthis, →II 39

accents, →II 177, 796

packages (*cont.*)

acro, →I 7, 30, 156–163, →II 811, 978

addlines, →I 416ff.

adorn, →II 118

adjustbox, →I 587, 595–601, 614, →II 813

afterpage, →I 519, 525

Alegreya, →I 662, 698, →II 11, 315

AlegreyaSans, →I 662, →II 11

algorrevived, →I 703, →II 90

algorithmicx, →I 322

algorithms, →I 322

algpseudocode, →I 322

alltt, →I 298

almdra, →II 100

amscd, →II 129, 160f.

amscfonts, →II 130, 226ff., 239f., 720

amsmath, →I 93, 116, 149f., 336, →II 116f., 127–156, 158, 163–171, 174, 175, 179–184, 190, 192ff., 196, 199–206, 208f., 220, 223, 244, 283, 639, 641, 711, 795

amsopn, →II 129, 193

amsrefs, →II 799

amssymb, →II 130, 149, 208–224, 226, 236, 239f.

amstext, →I 167, →II 129, 192

amsthm, →I 89, 92, 281–284, 285, 288, →II 129, 795

amsxtra, →II 129, 177

AnonymousPro, →II 90

antpolt, →II 47

anttor, →II 101, 295

apalike, →II 420, 429, 476

arabi, →II 323, 341

arabicfront, →I 26

arabluatex, →II 341

arimo, →II 69

array, →I 167, 436, 437–446, 454, 457, 466f., 469, 471, 476–493, 497, →II 157f., 599, 695, 784, 978

arydshln, →I 467, 469f.

asciilist, →I 295

askinclude, →I 30

astron, →II 429

atveryend *obsolete*,

→II 679, *see instead* hook management

authblk, →I 27f.

authordate1-4, →II 420, 429, 489

avant *obsolete*, →I 691, *see instead* tgadvantor

babel, →I 82, 91, 134, 152, 155, 157, 160, 184, 247,

Biographies

Frank Mittelbach

Frank's interest in the automated formatting of complex documents in general, and in \LaTeX in particular, goes back to his university days and has always been a major interest, perhaps a vocation, and throughout his IT career certainly a “second job”. He studied mathematics and computer science at the Johannes Gutenberg University, Mainz, and afterwards joined EDS, Electronic Data Systems, initially working in a newly formed group for document processing using \TeX and other tools and later on in the system management division.

At the \TeX Users Group (TUG) conference at Stanford University in 1989, he gave a talk about the (many) problems with \LaTeX 2.09, which led to him and a small team (known as the \LaTeX Project Team) to take on the responsibility for the further development and maintenance of \LaTeX from its original author Leslie Lamport.¹ In the capacity of technical lead of this project, he has overseen the original major release of \LaTeX 2 ϵ in 1994 and the 36 (as of this writing) subsequent releases of this software. Right now he and the team are working on the important multi-year project to make \LaTeX automatically produce tagged PDF and conform to accessibility standards.

When EDS was bought by HP he joined the global Enterprise Service Management division and eventually worked there as the European lead architect. In 2015 Frank ended his IT-industry career to fully concentrate on research in automated typesetting and Open Source software development, in particular on the future development of the \LaTeX typesetting system.

Stanford, 1989 ...

¹The history is briefly discussed in Section 1.1 of this edition; for a listing of all \LaTeX Project team members through the years see <https://latex-project.org/about/team/>.

Frank is author or coauthor of many and varied \LaTeX extension packages, such as $\mathcal{A}\mathcal{M}\mathcal{S}\text{-}\text{\LaTeX}$, doc, multicol, and NFSS: the New Font Selection Scheme. His publication of many technical papers on \LaTeX and on general research results in automated formatting brought him in contact with Peter Gordon from Addison-Wesley. Peter and Frank inaugurated the book series *Tools and Techniques for Computer Typesetting* (TTCT), with Frank as series editor. *The \LaTeX Companion* (1994) was the first book of this series, which now includes titles that cover \LaTeX in all its facets.

... and three decades later

He is on the board of the International Gutenberg Society, an international association for the study of the history and development of printing technology and font-oriented media, where he focuses on the more recent period. He is also involved in the print production of the society and in general enjoys designing and typesetting high-quality documents using computers but also using traditional letterpress. One of his plans after finishing TLC3 is to typeset a book on Japanese authored by Peter Gordon. When not involved with typographical questions or programming Frank enjoys reading (though the books better be of high quality in content *and* form), listening to or playing music (he is an amateur bass player), and winning or losing board games, these days often collaborative ones.

He and his wife Christel live in the Gutenberg city of Mainz; their three grown-up sons have left by now for new pastures.

Ulrike Fischer

Ulrike Fischer studied mathematics at the University of Bonn. She wrote her thesis in a rather arcane branch called model theory with an Atari text processor called Signum but did not like to have to place lots of sub and superscripts with a mouse. So when seeing an example \LaTeX document, she directly ordered the floppy discs and never looked back.

Quite early she got interested in the internal handling of fonts and in chess typesetting as she wanted to print the bulletins of chess competitions she organized in her club.

With the help of the first edition of the *\LaTeX Companion*, she wrote the chessfss package, which allows users to choose between various chess fonts, and other chess-related packages.

After university, she moved with her husband to Siegburg and later to Mönchengladbach and worked as an assistant for a deputy of the state parliament of North Rhine-Westphalia. She found her way into the \LaTeX groups on the Internet and enjoyed answering questions and debugging errors. She also helped her father who after his retirement as a professor for computer science wrote with \LaTeX a number of books about Salvador Dalí's illustrations of the *Divine Comedy*. So when her job ended after a lost election, she decided to try something new and to work as a \LaTeX consultant.

Her interest in fonts continued over the years and led her to accept the job of maintaining luaotfload. Talks about accessibility and tagged PDF at Dante and TUG meetings induced her to work on the tagpdf package and to present it to L^AT_EX team members at a workshop at the TUG meeting in Rio de Janeiro. Both together got her an invite to join the team in 2018. She had already had many online contacts with the team members in Usenet groups and chats as well as in person — she met Frank the first time at a Dante meeting in Heidelberg, where she talked about how to misuse biblatex as an address database, and he showed her how to eat some Japanese dish — and so accepted without hesitation. She now lives with her husband Gert in Bonn.

Javier Bezos

Javier Bezos is passionate about typography, science, language, and writing systems, as well as about computer programming. A curious person and self-taught by nature, his interests are broad, and he has worked in fields like book and journal publishing, design, radio, and classical music. He is an honorary member of the Unión de Correctores, the Spanish professional association of copyeditors.

As a computer programmer, he has developed systems for both L^AT_EX and InDesign, including tools for technical documentation, automatic typesetting and copyediting, XML, and localization. It is this last facet that he develops most actively as a member of the L^AT_EX Project Team.

Javier has participated as an author on several style manuals and published the book *Tipografía y notaciones científicas*. He is currently working at FundéuRAE, a foundation linked to the Royal Spanish Academy.

Hiking, reading old science books, and watching classic movies are some of his hobbies.

Johannes Braams

Johannes Braams studied electronic engineering at the Technical University in Enschede, the Netherlands. His master's thesis was on video coding, based on a model of the human visual system. During his research at the *dr. Neher Laboratories* in 1984, he came into contact with L^AT_EX for the first time. He was a founding board member of the Dutch-speaking TeX User Group (NTG) in 1988 and participated in developing support for typesetting Dutch documents. He started work on developing the babel system for multilingual typesetting following the Karlsruhe EuroT_EX conference in 1989.

Since its inception at the EuroT_EX conference in Cork in 1990, he has been a member of the L^AT_EX Project Team. Johannes still maintains a couple of L^AT_EX extension

packages such as the `ntgclass` family of document classes and the `supertabular` and `changebar` packages.

After his studies, Johannes continued to work for the Dutch PTT, which later came to be known as KPN until 2014, mostly as an IT project manager. In 2015 he started a new career as a consultant on cybersecurity for industrial automation and control systems, first at the Software Improvement Group in Amsterdam; then in 2017 he joined Royal HaskoningDHV, a Dutch engineering firm that operates globally. He works on security by design in industrial installations. Johannes is now a board member of the Dutch chapter of (ISC)². He lives with his wife in Den Ham; their two sons both graduated from the University Twente in Enschede.

Joseph Wright

Joseph Wright is a synthetic chemist who studied for his degree at the University of Leicester before moving to the University of Cambridge for his PhD. He first heard of \LaTeX in about 2001 but did not start using it until writing a final report on his first research assistant position at the University of Southampton in 2004.

Joseph transitioned from being a user to a developer most obviously when he answered a “simple” question on the `comp.text.tex` newsgroup asking for a fix to the `Slunits` package in 2007. It soon turned out that this was the tip of a much larger task: writing a truly comprehensive units package: `siunitx`.

Joseph became involved with the \LaTeX Project Team’s work after Will Robertson asked him what he thought of the experimental ideas in `expl3`. Joseph liked them, so he used `expl3` to develop the second version of `siunitx` and raised *lots* of questions about how things worked. His questions and suggestions led to an invite to join the team.

As well as writing (\LaTeX) code, Joseph is one of the moderators on the $\text{\TeX}/\text{\LaTeX}$ StackExchange site. He’s one of two moderators who’ve been in place from the very start of the site, helping to ensure there’s always been a welcoming approach with the aim of helping end users solve their (\LaTeX) problems.

Production Notes

This book was typeset using the \LaTeX document processing system (which it describes) together with substantial help from some of the extension packages covered herein, and considerable extra ad hoc \LaTeX programming effort. We used the base \LaTeX release dated 2022-11-01, pdf \TeX as the main \TeX engine, and Lua \TeX for examples that involved OpenType fonts. All packages have been taken from the 2022 \TeX Live distribution to ensure that the examples show what you will get when you run them yourself.¹

The text body fonts used are Lucida Bright and Lucida Sans (Bigelow/Holmes) at 8.47pt/11.72pt. These font families can be used at rather small sizes, which can be seen by the fact that the monospaced font we matched them with is Latin Modern Typewriter (\TeX Gyre foundry) at 10.36pt. This particular combination was chosen to get a reasonable amount of material on each page and to optically balance the appearance of the `typewriter` font so that it is distinguishable but without too big a contrast.

Body fonts

The text in the examples mostly uses \TeX Gyre’s Times Roman (`tgtermes`) with its Helvetica (`tgheros`) for sans serif. For the mathematical material in the examples we stayed with the now classic Computer Modern math fonts, so the symbols will appear familiar to the majority of mathematics users. Of course, examples intended to demonstrate the use of other fonts are exceptions.

Example fonts

Package usage in the book

If you count the examples as part of the book, then every package described in this edition has also been used in it. This is a bit of a red herring, though, because the examples are typeset as separate documents and the results are then included in the book as PDF (Portable Document Format) images. However, many of the packages

*The \LaTeX packages
used to produce the
book ...*

¹Well, at least initially — sometimes, though seldom, packages change in incompatible ways.

have been deployed for real to produce this edition, and for the interested reader we now list the most important ones and why they have been used.

To help in producing the explanatory text we used `acro` for acronyms, resetting their use count on a per-chapter basis. Thus, for most acronyms you see the first use in a chapter being displayed in its full form, e.g., as “Comprehensive T_EX Archive Network (CTAN)”. For quotation marks, commands from the `csquotes` package have been used throughout.

Heavy use was made of `\vref` and friends from the `varioref` package. We often refer to examples or sections “on the facing page”, “previous”, “next” or “below”, etc., and in all such cases these are generated texts and not hardwired in the source. Otherwise, the layout process would have been a nightmare, requiring extensive amounts of textual adjustments whenever material moved from one page to the next and vice versa. Of course, using `varioref` in a book of this size is bound to produce an *impossible document* as explained on page –I 85. And indeed, it happened a handful of times that the generated text got split across two pages, rendering the wrong result in all cases. Initially, we changed the errors to warnings and ignored them, and then resolved the issues during the final pagination by adjusting the surrounding text (either rewriting parts or adding some strategic line or page breaks).

Since the second edition of *The L^AT_EX Companion* we used “hanging punctuation” to typeset the paragraphs. In the last edition, this typographical icing was basically produced manually, but this time we have been fortunate to simply¹ apply the `microtype` package. This package was also used to add some light expansion/suppression using the *hz*-algorithm, which, in my opinion noticeably improved the overall look and feel of the paragraphs. For comparison, look at this paragraph and compare it with the repeat below (where both features are turned off).

Since the second edition of *The L^AT_EX Companion* we used “hanging punctuation” to typeset the paragraphs. In the last edition, this typographical icing was basically produced manually, but this time we have been fortunate to simply¹ apply the `microtype` package. This package was also used to add some light expansion/suppression using the *hz*-algorithm, which, in my opinion noticeably improved the overall look and feel of the paragraphs. Compare this to the previous paragraph (which has both features turned on) — *which do you prefer?*

The core design for the book dates back to the first edition and therefore chapter headings, list environments, etc., have been defined using the basic mechanisms of L^AT_EX rather than using support packages because those were not available back then. For the running headers and the page numbers the `fancyhdr` package was used.

To produce the various tables in the book, `array` and `tabularx` (for the extended syntax) were put to good use and on nearly every table we applied commands from the `booktabs` package for the formal rules. The few multipage tables have been generated with `longtable` and in some places we used `multicol` to produce a table-like appearance.

¹We had to define our own configuration file, though, because the `microtype` package has no presets for the commercial Lucida Bright fonts and the default settings, while more or less adequate, were not totally satisfactory. Thus, we applied the advice given in Section 3.1.3.

²The paragraph now breaks differently and the margins are no longer optically aligned.

Graphics have been included with the help of `graphicx` and in a few places we used `overpic` to add some arrows or other data to the image. The captions have been styled with the `caption` package; other float-related packages were not necessary as the book requirements have been fairly light. Producing the examples, showing input and output side by side, was more elaborate and involved the use of the `fancyvrb` package and a fair amount of programming. The general approach we used is explained in Section 4.2.4 on page →I315.

... showing graphics and examples ...

The boxes showing information that is only relevant for Unicode engines or that detail differences between the `LaTeX` and `lualatex` approach have been designed using `tcolorbox`, which in turn uses `tikz`.

... displaying informational boxes ...

For the bibliography we used `LaTeX` with a number-only style that was designed with the help of `custom-bib`, and `natbib` was used for the citations. Because this edition was split in two parts, each part got its own bibliography; this was achieved with the `bibunits` package.

... producing the bibliography ...

The book uses several separate indexes (even though only two are shown in the final product). To generate the raw data for them we made use of the `index` package and the sorting was done with `MakeIndex`. However, due to the complexity of the index (the colored page numbers, etc.) it was necessary to use pre- and post-processing by scripts to produce the final form of the index files. These were then typeset using an enhanced version of the `multicol` package to add the continuation lines — something that perhaps one day can be turned into a proper package. The “Commands and Concepts” index is a mixture of commands, environments, and other `LaTeX` elements, but also includes concept entries. The latter were produced by typesetting a version of the book with line numbers and giving that to the indexer, who produced “conceptual index entries” that were then added to the source files for the book so that pagination changes would not invalidate the index entries. This was a major testament to the quality of the `lineno` package, as it worked “straight out of the box”.

... the different indexes ...

In anticipation of a PDF and ebook version of the third edition, we already used both the `bookmark` and the `hyperref` package. Even though this does not show in the printed form of the book it helped us tremendously during its preparation, because all internal references have been active links, allowing us to quickly jump from one place to another in the draft PDF document. Furthermore, all internal notes we made were enhanced to generate bookmarks so that the bookmark pane of the PDF reader gave us a quick overview of all the tasks still to do and text still to write.

... and interactive PDF features

Packages that should have been used for the book ...

You might be surprised that some heavily recommended packages, such as `enumitem` or `geometry`, are missing. The reason is simply that the fundamental design decisions, e.g., the page layout or the design of the headings, lists, etc., have been retained across all editions and when the first edition was typeset in 1994 those packages that can now make your life easier were not yet available, and thus the necessary code had to be handcrafted. Altering that setup was only done when improvements or changes were necessary; e.g., the `titletoc` package was added when we introduced the partial TOCs below the chapter headings. But in a new project such packages would have been used from the start.

... but have not

Packages supporting the production

*Running out of files
to write to*

This book loads more than 140 .sty files (not counting those loaded in the examples), which is way beyond what is needed in typical documents. Several of these packages open their own write streams, and this is a rather limited resource in T_EX (only 16 can be open at the same time). As a result the book died when processing the list of figures because that tried to open one stream too many. Fortunately, there is a remedy with Bruno Le Floch's `morewrites` package. It comes with a cost, though, because it needs additional processing time, but the important point is that it enables you to process a document of such complexity!

Color woes

The printing process for the book required two colors: black and some kind of blue as a spot color. For this, we used the packages `xcolor` and `colorspace`, but it is not a simple task to ensure that the final document does not contain color instructions in CMYK (or RGB) because some packages include hardwired color specifications using such models. As a result we had to do some patching or avoid using color in a few examples in order to not upset the final production process. This is clearly an area where L^AT_EX could be improved to make life easier.

Task management

To keep track of all the open tasks that needed resolving, we used the `todonotes` package and defined a few commands similar to those shown in Example A-1-17 on page 645, except that we also added a bookmark for each task using the `bookmark` package. At one point this showed several hundred entries, but now as I write this text it is thankfully down to a handful of remaining tasks.

*Where are my
errors?*

Loading the `structuredlog` package enabled us to quickly identify in which source file an error occurred — not that we ever had any.¹ The footnote in Appendix B.1 on page 712 explains how to make use of this package.

*Controlling the
source*

Using a source control approach is beneficial for nearly every project — for a complex one like this book, it is essential. It enables you and your co-authors to work without stepping on each other's toes; if something breaks, you have a history that helps you identify and resolve problems; and, last but not least, it simplifies project data synchronization across different devices and locations. For the second edition we used SVN; for this edition it was Git, and the package `gitinfo2` was deployed to write source branch and date information at the bottom of every page (outside the final printing area).

Tracking file usage

Another tool we used regularly was `mkjobtexmf`. With its help we collected all files used during compilation in a separate tree, which was also placed under source control. This way, any updates to standard packages, font files, etc., could be easily tracked, which again helped a lot if something went awry.

The production cycle

The production of this book required a custom class and, as outlined above, many additional package files. It also needed a complex “make” process using a collection of “shell scripts” controlled by a “Makefile”. One of the major tasks these accomplished

¹ Joke — of course, we did. All kinds of errors occurred, from simple typos to subtle package incompatibilities that resulted in talking to the developers after identifying the root cause of the problem.

was to ensure that the typeset output of each and every example really is produced by the accompanying example input. This “make” process worked as follows:

- When first processing a chapter, \LaTeX generated a source document file for each example. These are the one-and-a-half-thousand “example files” you will find on CTAN at <https://ctan.org/pkg/tlc3-examples>. *Generating examples*
- The make process then ran each of these “example files” through \LaTeX (also calling \BibTeX , \biber , or whatever else was needed) as often as was necessary to produce the final form of the typeset output.

The resulting PDF file was post-processed with `pdftocrop` to drop all white space on the outside (making the PDF pages only as big as the visible output) and, if necessary, to split it into separate pages using `pdfseparate`.

- The next time \LaTeX was run on that chapter, each of these PDF output files was automatically placed in its position in the book, next to (or near) the example input. The process was not complete even then because the horizontal positioning of some elements, in particular the examples, depends on whether they are on a verso or recto (the technique from Example A-5-7 on page 692 was used in this case). Thus, at least one or two additional runs were needed before all the cross-references were correctly resolved and \LaTeX finally found the right way to place the examples correctly into the margins.

Due to the example-generating complexity — together with the use of `varioref` altering the generated text based on distance to the referenced object — the book required not the usual two or three but in fact six complete runs before \LaTeX stopped asking for “Rerun to get cross-references right”. Even on a fast iMac from 2021 with an M1 chip, that meant a half-hour wait — and this is not counting the generation of the 1540 examples. Those required another two-and-a-half hours¹ so that it took a total of three hours of computer-processing time to produce the typeset book from scratch.

The layout effort

That was about as far as automation of the process could take us. Because of the many large examples that could neither be broken nor treated as floating material, getting good page breaks turned out to be a major challenge. For this and other reasons, getting to the final layout of the book was fairly labor intensive and even required minor rewriting (on maybe 10% of the pages) in order to avoid bad line breaks or page breaks (e.g., paragraphs ending with a single-word line or a distracting hyphenation at a page break). Spreads were allowed to run one line long or one line short if necessary, and in several cases the layout and contents of the examples were manually adjusted to allow decent page breaks.

A great help in this final layout process was the package `widows-and-orphans`, which told us the pages that contained widows, orphans, or hyphenations across page boundaries. We then applied one of the suggestions from Section 5.6.6 on page →I 422, often adding an explicit page break in some strategic place or sometimes rewriting a

Manual labor from page 1 to 2000

Giving widows and orphans a new home

¹The main factor here is the file I/O cost. Each example has to be run several times, and each time, \TeX has to start and load all packages and fonts, over and over again.

paragraph to make it longer or shorter (after all, we are the authors and can change the text for aesthetic reasons). In a few places, no fix seemed reasonable, in which case we accepted an orphan or widow and marked the place with `\WaOignorenext`. In total, 1.5% of the pages were treated like this.

Some pagination statistics

Here are a few approximate statistics from this page layout process: 24 long spreads, 41 short spreads, 51 compressed pages (using `\enlargethispage*`) combined with forced page breaks. This is noticeably less than in the previous edition and one of the reasons is that this time we made ample use of \TeX 's `\looseness` functionality: we ran 125 paragraphs one line shorter than normal and 17 paragraphs one line longer than is optimal in \TeX 's eyes.

We added 501 forced page breaks in total, which means 25% of all pages have a forced premature ending — usually to avoid half-empty pages later due to a larger example showing up in the wrong place. While I think the results are satisfactory, getting this right was rather time consuming and difficult — here it really hurts that \TeX has a global paragraph optimizer but generates its pagination with a simple greedy algorithm. While this gives reasonable results with most documents it totally breaks down in those that contain larger unbreakable parts such as this book.¹

Searching across the final sources, there are about 1200 adjustments to the vertical spacing² and 100 other manual adjustments (other than rewriting or altering the examples). For the latter I do not have any reliable data, but from my recollection I would guess that about a quarter (i.e., 400) of the examples have been adjusted to better blend into the page flow.

A final word of advice 

In several places in the book we have given the advice to leave any layout work until the very last minute, and on the whole we followed our advice to the letter with this book. For example, all pagination work was delayed until the copy editor had worked through all chapters and marked up all the mistakes we made (well, hopefully all) — it took me a while to convince her not to mark up ugly-looking page breaks, because they were deliberate. Given that changing a single letter in a paragraph may result in total reflow (and possibly a different number of lines) this saved me a lot of unnecessary work.

However, in one case I diverged from that principle. When I started to write this section, I realized that the chosen typewriter font seemed to be a tiny bit too large compared to the Lucida body fonts. I therefore decided to scale it down by one percent. Given that this is only used for individual words, I expected a few changes but not much. To my dismay I ended up with more than fifty pages where the pagination was totally broken, e.g., paragraphs getting shorter or longer, lines overflowing to the next page, etc. It took me a full day to repair the damage. So again, take this advice seriously and only work on pagination adjustments when you are 100% done with the text and all your other layout choices have been made — easier said than done, I know!

¹I had secretly hoped that the research results outlined in [134, 135, 138] could already be applied to the production of this book, which would have saved me perhaps a month worth of effort. Unfortunately, turning the prototype into a fully working production system proved to be more complicated than I had bargained for. Thus, in the end I buried the idea and produced the layout the old-fashioned way.

²These adjustments are partially due to deficiencies in parameter setup for the custom class. However, by the time I realized this, several chapters had already been paginated and changing the class setup would have invalidated those. Thus, it seemed simpler to live with the imperfection.

PDF and ePub production

As you know, we had to split the third edition — due to its size — into two physical books. However, both parts were produced with a single \LaTeX source to make it easier for \LaTeX (and us) to automatically resolve cross-references across the parts and to generate a consolidated index with entries for the whole edition. This index was included at the end of each physical part to make it easier for our readers to work with the two books.

*The PDF for printing
the edition*

The tables of contents lists were tailored for each part: they show the sections of the current part in detail, but only give a chapter-level overview of the other part. Similarly, the bibliographies at the end of each part only show entries that have a citation in that part. The few books and articles that are referenced in both parts therefore appear twice in the complete print edition. This way the resulting PDF only needed to be split in the middle and sent to the printer.

However, in that form the PDF is unsuitable as a digital product or as a basis for producing an ePub of the complete edition, because it contains a duplicated index, two separate bibliographies, and no consolidated front matter, e.g., no complete table of contents or list of figures.

Thus, for the digital version we augmented the \LaTeX sources so that by flipping a switch a slightly different PDF is produced. The differences between the print version and the digital version are as follows:

*The PDF for digital
consumption*

- In the digital version the front matter of Part I contains a consolidated table of contents for both parts and the partial table of contents in Part II was dropped. The same applies to the list of figures and the list of tables.
- The bibliographies from both parts were combined and placed at the end of Part II. Of course, this alters the citation labels within the edition, and that may result in a slightly different paragraph formatting in one or the other place (due to differently sized labels), but great care was taken to not affect the overall pagination. Thus, if you own both the print and the digital edition they show the same material on pages with the same page number.
- The bibliography change also required me to regenerate two examples: 3-4-17 on page →I 189 and 4-1-44 on page →I 288, because they both refer to entries in the bibliography. These examples therefore differ slightly between the print and the digital versions.
- The preface of Part II was shortened because it repeated the “How to work with the book” section, which is not needed twice in the digital version.
- For the same reason the index for the complete edition at the end of Part I was dropped and only the complete index in Part II was kept. This index of the digital version should be more or less identical to the one in the print version, e.g., you can use the digital index and then look up the page in the printed book. However, given that we dropped one section from the preface that contained index entries, the index in the printed book has a few more page references.
- This section about PDF and ebook production only appears in the digital version.

In all other respects the print and the digital versions have been kept identical, e.g., the page numbers are restarted in Part II, so that most page numbers appear twice. This way they are at most three digits wide and it remains possible to correctly cite pages from the edition, regardless of somebody owning the digital or the print version (with the exception of pages from the front or the back matter).

*Navigating
the PDF*

Most PDF viewers allow you to select pages by entering, for example, II–39. Thus, if somebody tells you to have a look at the nice Accanthis font on page 39 in Part II and you want to look this up in the PDF version, this is a simple way to reach that page. Of course, in the ePub version page numbers are of no real help, except that if used in the text they contain a link that you can click on to jump to the correct place in the edition. In the ePub you have to navigate using the book marks if you want to get to a specific section — a possibility that, of course, exists in the PDF as well.

*Producing the
ePub version*

This altered PDF is what you get as one of the digital products, and it is also the one that was used as a basis for producing the ePub version by a company specializing in such work. There are in fact tools in the \LaTeX world, such as `tex4ht` by Michal Hoftich or `lwarp` by Brian Dunn that assist you in a direct conversion of \LaTeX sources to HTML or ePub, but the *\LaTeX Companion* is so complicated that we did not attempted to use the direct route. Maybe that is going to change in a future edition, when \LaTeX is fully capable of automatically producing a tagged PDF.

*Using the
ePub version*

The ePub version offers another specialty: if you double-click on an example or on some code fragment then you are taken to a separate page showing you that part on its own without any margins, i.e., noticeably larger. A “Done” button on that page brings you back to the point where you started from even if your viewer does not offer a convenient way back as part of its controls. Thus, while some examples might appear to be somewhat small if viewed together with the surrounding text, they can be easily enlarged, if necessary.
